1 Diameter Users Guide

The diameter application is a framework for building applications on top of the Diameter protocol.

1.1 Introduction

The diameter application is an implementation of the Diameter protocol as defined by RFC 6733. It supports arbitrary Diameter applications by way of a dictionary interface that allows messages and AVPs to be defined and input into diameter as configuration. It has support for all roles defined in the RFC: client, server and agent. This chapter provides a short overview of the application.

A Diameter node is implemented by configuring a service and one or more transports using the interface module diameter. The service configuration defines the Diameter applications to be supported by the node and, typically, the capabilities that it should send to remote peers at capabilities exchange upon the establishment of transport connections. A transport is configured on a service and provides protocol-specific send/receive functionality by way of a transport interface defined by diameter and implemented by a transport module. The diameter application provides two transport modules: diameter_tcp and diameter_sctp for transport over TCP (using gen_tcp) and SCTP (using gen_sctp) respectively. Other transports can be provided by any module that implements diameter's transport interface.

While a service typically implements a single Diameter node (as identified by an Origin-Host AVP), transports can themselves be associated with capabilities AVPs so that a single service can be used to implement more than one Diameter node.

Each Diameter application defined on a service is configured with a callback module that implements the application interface through which diameter communicates the connectivity of remote peers, requests peer selection for outgoing requests, and communicates the reception of incoming Diameter request and answer messages. An application using diameter implements these application callback modules to provide the functionality of the Diameter node(s) it implements.

Each Diameter application is also configured with a dictionary module that provide encode/decode functionality for outgoing/incoming Diameter messages belonging to the application. A dictionary module is generated from a dictionary file using the diameterc utility. Dictionaries for the RFC 6733 Diameter Common Messages, Base Accounting and Relay applications are provided with the diameter application.

1.2 Usage

To be written.

1.3 Examples

Example code can be found in the diameter application's examples subdirectory.

1.4 Standards Compliance

The table below summarizes the diameter application's compliance with RFC 6733. Since the diameter application isn't a Diameter node on its own, compliance is strictly the responsibility of the user in many cases, diameter providing the means for the user to be compliant rather than being compliant on its own.
The Compliance column notes C (Compliant) if the required functionality is implemented, PC (Partially Compliant) if there are limitations, NC (Not Compliant) if functionality is not implemented, or a dash if text is informational or only places requirements that must be met by the user's implementation.

Capitalized Diameter refers to the protocol, lowercase diameter to the Erlang application.

### 1.4.1 RFC 6733 - Diameter Base Protocol

### 1.4 Standards Compliance

| 1.3.3 | Creating New Commands | — | New commands can be defined using the dictionary interface. |
| 1.3.4 | Creating New Diameter Applications | — | New applications can be defined using the dictionary interface. |
| 2 | Protocol Overview | — | Session state is the responsibility of the user. The role of a Diameter node is determined by the user's implementation. |
| 2.1 | Transport | PC | Ports are configured by the user: diameter places no restrictions. The transport interface documented in `diameter_transport(3)` allows the user to implement their own methods. Ready support is provided for TCP, TCP/TLS, and SCTP, but not DTLS/SCTP. Multiple connections to the same peer is possible. ICMP messages are not interpreted. |
| 2.1.1 | SCTP Guidelines | C | Unordered sending is configurable in `diameter_sctp(3)`. There is no special handling of DPR/DPA: since a user that cares about pending answers should wait for them before initiating DPR. A PPID can be configured with a `gen_sctp sctp_default_send_param` option. |

Table 4.1: RFC 6733 Compliance
2 Reference Manual

The Diameter application is a framework for building applications on top of the Diameter protocol.
This module provides the interface with which a user can implement a Diameter node that sends and receives messages using the Diameter protocol as defined in RFC 6733.

Basic usage consists of creating a representation of a locally implemented Diameter node and its capabilities with `start_service/2`, adding transport capability using `add_transport/2` and sending Diameter requests and receiving Diameter answers with `call/4`. Incoming Diameter requests are communicated as callbacks to a `diameter_app(3)` callback modules as specified in the service configuration.

Beware the difference between `diameter` (not capitalized) and `Diameter` (capitalized). The former refers to the Erlang application named diameter whose main api is defined here, the latter to Diameter protocol in the sense of RFC 6733.

The diameter application must be started before calling most functions in this module.

### DATA TYPES

- `Address()`
- `DiameterIdentity()`
- `Grouped()`
- `OctetString()`
- `Time()`
- `Unsigned32()`
- `UTF8String()`

Types corresponding to RFC 6733 AVP Data Formats. Defined in `diameter_dict(4)`.

- `application_alias() = term()`
  
  Name identifying a Diameter application in service configuration. Passed to `call/4` when sending requests defined by the application.

- `application_module() = Mod | [Mod | ExtraArgs] | #diameter_callback{}`

  Module implementing the callback interface defined in `diameter_app(3)`, along with any extra arguments to be appended to those documented. Note that extra arguments specific to an outgoing request can be specified to `call/4`, in which case those are appended to any module-specific extra arguments.

  Specifying a `#diameter_callback{}` record allows individual functions to be configured in place of the usual `diameter_app(3)` callbacks. See `diameter_callback.erl` for details.

- `application_opt()`

  Options defining a Diameter application. Has one of the following types.

  - `{alias, application_alias()}
    
    Unique identifier for the application in the scope of the service. Defaults to the value of the `dictionary` option.

  - `{dictionary, atom()}
    
    Name of an encode/decode module for the Diameter messages defined by the application. These modules are generated from files whose format is documented in `diameter_dict(4)`.
{module, application_module()}
Callback module in which messages of the Diameter application are handled. See `diameter_app(3)` for the required interface and semantics.

{state, term()}
Initial callback state. The prevailing state is passed to some `diameter_app(3)` callbacks, which can then return a new state. Defaults to the value of the alias option.

{call_mutates_state, true|false}
Whether or not the `pick_peer/4` application callback can modify the application state. Defaults to false.

**Warning:**
pick_peer/4 callbacks are serialized when this option is true, which is a potential performance bottleneck. A simple Diameter client may suffer no ill effects from using mutable state but a server or agent that responds to incoming request should probably avoid it.

{answer_errors, callback|report|discard}
Manner in which incoming answer messages containing decode errors are handled.
If `callback` then errors result in a `handle_answer/4` callback in the same fashion as for `handle_request/3`, with errors communicated in the `errors` field of the `#diameter_packet{"}` passed to the callback. If `report` then an answer containing errors is discarded without a callback and a warning report is written to the log. If `discard` then an answer containing errors is silently discarded without a callback. In both the `report` and `discard` cases the return value for the `call/4` invocation in question is as if a callback had taken place and returned `{error, failure}`.

Defaults to `discard`.

{request_errors, answer_3xxx|answer|callback}
Manner in which incoming requests are handled when an error other than 3007 (DIAMETER_APPLICATION_UNSUPPORTED, which cannot be associated with an application callback module), is detected.
If `answer_3xxx` then requests are answered without a `handle_request/3` callback taking place. If `answer` then even 5xxx errors are answered without a callback unless the connection in question has configured the RFC 3588 common dictionary as noted below. If `callback` then a `handle_request/3` callback always takes place and its return value determines the answer sent to the peer, if any.

Defaults to `answer_3xxx`.

**Note:**
Answers sent by diameter set the E-bit in the Diameter Header. Since RFC 3588 allows only 3xx result codes in an answer-message, answer has the same semantics as `answer_3xxx` when the transport in question has been configured with `diameter_gen_base_rfc3588` as its common dictionary. Since RFC 6733 allows both 3xx and 5xx result codes in an answer-message, a transport with `diameter_gen_base_rfc6733` as its common dictionary does distinguish between `answer_3xxx` and `answer`.

call_opt()
Options available to `call/4` when sending an outgoing Diameter request. Has one of the following types.
Extra arguments to append to callbacks to the callback module in question. These are appended to any extra
arguments configured on the callback itself. Multiple options append to the argument list.

Filter to apply to the list of available peers before passing it to the pick_peer/4 callback for the application
in question. Multiple options are equivalent a single all filter on the corresponding list of filters. Defaults
to none.

Peer to which the request in question can be sent, preempting the selection of peers having advertised support
for the Diameter application in question. Multiple options can be specified, and their order is respected in
the candidate lists passed to a subsequent pick_peer/4 callback.

Number of milliseconds after which the request should timeout. Defaults to 5000.

detach

Cause call/4 to return ok as soon as the request in question has been encoded, instead of waiting for and
returning the result from a subsequent handle_answer/4 or handle_error/4 callback.

An invalid option will cause call/4 to fail.

capability()

AVP values sent in outgoing CER or CEA messages during capabilities exchange. Can be configured both on a
service and a transport, values on the latter taking precedence. Has one of the following types.

-Origin-Host', DiameterIdentity()
-Origin-Realm', DiameterIdentity()
-Host-IP-Address', [Address()]

An address list is available to the start function of a transport module, which can return a new list for use
in the subsequent CER or CEA. Host-IP-Address need not be specified if the transport module in question
communicates an address list as described in diameter_transport(3)

-Vendor-Id', Unsigned32()}
'Result-Name', UTF8String()
-Origin-State-Id', Unsigned32()}

Origin-State-Id is optional but, if configured, will be included in outgoing CER/CEA and DWR/DWA
messages. Setting a value of 0 (zero) is equivalent to not setting a value, as documented in RFC 6733. The
function origin_state_id/0 can be used as to retrieve a value that is computed when the diameter application
is started.

-Supported-Vendor-Id', [Unsigned32()]
-Supported-Application-Id', [Unsigned32()]
-Inband-Security-Id', [Unsigned32()]

Inband-Security-Id defaults to the empty list, which is equivalent to a list containing only 0
(NO_INBAND_SECURITY). If 1 (TLS) is specified then TLS is selected if the CER/CEA received from
the peer offers it.

-Acct-Application-Id', [Unsigned32()]
-Vendor-Specific-Application-Id', [Grouped()]
-Firmware-Revision', Unsigned32()}

Note that each tuple communicates one or more AVP values. It is an error to specify duplicate tuples.
An expression that can be evaluated as a function in the following sense.

```erl
eval([{M,F,A} | T]) ->
    apply(M, F, T ++ A);
eval([F|A] | T) ->
    eval([F | T ++ A]);
eval([F|A]) ->
    apply(F, A);
eval(F) ->
    eval([F]).
```

Applying an `eval()` E to an argument list A is meant in the sense of `eval([E|A])`.

**Warning:**

Beware of using fun expressions of the form `fun Name/Arity` in situations in which the fun is not short-lived and code is to be upgraded at runtime since any processes retaining such a fun will have a reference to old code. In particular, such a value is typically inappropriate in configuration passed to `start_service/2` or `add_transport/2`.

**peer_filter() = term()**

Filter passed to `call/4` in order to select candidate peers for a `pick_peer/4` callback. Has one of the following types.

- none
  - Matches any peer. This is a convenience that provides a filter equivalent to no filter.
- host
  - Matches only those peers whose Origin-Host has the same value as Destination-Host in the outgoing request in question, or any peer if the request does not contain a Destination-Host AVP.
- realm
  - Matches only those peers whose Origin-Realm has the same value as Destination-Realm in the outgoing request in question, or any peer if the request does not contain a Destination-Realm AVP.
- \{host, any\|DiameterIdentity()\}
  - Matches only those peers whose Origin-Host has the specified value, or all peers if the atom any.
- \{realm, any\|DiameterIdentity()\}
  - Matches only those peers whose Origin-Realm has the specified value, or all peers if the atom any.
- \{eval, eval()\}
  - Matches only those peers for which the specified eval() returns true when applied to the connection's diameter_caps record. Any other return value or exception is equivalent to false.
- \{neg, peer_filter()\}
  - Matches only those peers not matched by the specified filter.
- \{all, [peer_filter()]\}
  - Matches only those peers matched by each filter in the specified list.
- \{any, [peer_filter()]\}
  - Matches only those peers matched by at least one filter in the specified list. The resulting list will be in match order, peers matching the first filter of the list sorting before those matched by the second, and so on.
Like any, but stops at the first filter for which there are matches, which can be much more efficient when there are many peers. For example, the following filter causes only peers best matching both the host and realm filters to be presented.

\{first, \{all, \{host, realm\}, realm\}\}

An invalid filter is equivalent to \{any, []\}, a filter that matches no peer.

**Note:**

The host and realm filters cause the Destination-Host and Destination-Realm AVPs to be extracted from the outgoing request, assuming it to be a record- or list-valued `diameter_codec:message()`, and assuming at most one of each AVP. If this is not the case then the \{host\} realm, `DiameterIdentity()`过滤器 must be used to achieve the desired result. An empty `DiameterIdentity()` (which should not be typical) matches all hosts/realms for the purposes of filtering.

**Warning:**

A host filter is not typically desirable when setting Destination-Host since it will remove peer agents from the candidates list.

```
service_event() = \#diameter_event\(service = service_name(), info = service_event_info()\)
```

An event message sent to processes that have subscribed to these using `subscribe/1`.

```
service_event_info() = term()
```

The info field of a `service_event()` record. Can have one of the following types.

```
start
stop
```

The service is being started or stopped. No event precedes a `start` event. No event follows a `stop` event, and this event implies the termination of all transport processes.

```
{up, Ref, Peer, Config, Pkt}
{up, Ref, Peer, Config}
{down, Ref, Peer, Config}
```

Ref = `transport_ref()`  
Peer = `diameter_app:peer()`  
Config = `{connect|listen, \{transport_opt()\}\}`  
Pkt = `#diameter_packet()`

The RFC 3539 watchdog state machine has transitioned into (up) or out of (down) the OKAY state. If a `#diameter_packet()` is present in an `up` event then there has been a capabilities exchange on a newly established transport connection and the record contains the received CER or CEA.

Note that a single `up` or `down` event for a given peer corresponds to multiple `peer_up/3` or `peer_down/3` callbacks, one for each of the Diameter applications negotiated during capabilities exchange. That is, the event communicates connectivity with the peer as a whole while the callbacks communicate connectivity with respect to individual Diameter applications.
{reconnect, Ref, Opts}

<table>
<thead>
<tr>
<th>Ref = transport_ref()</th>
</tr>
</thead>
<tbody>
<tr>
<td>Opts = [transport_opt()]</td>
</tr>
</tbody>
</table>

A connecting transport is attempting to establish/reestablish a transport connection with a peer following `connect_timer` or `watchdog_timer` expiry.

{closed, Ref, Reason, Config}

<table>
<thead>
<tr>
<th>Ref = transport_ref()</th>
</tr>
</thead>
<tbody>
<tr>
<td>Config = {connect</td>
</tr>
</tbody>
</table>

Capabilities exchange has failed. `Reason` can have one of the following types.

{'CER', Result, Caps, Pkt}

| Result = ResultCode | {capabilities_cb, CB, ResultCode|discard} |
|----------------------|-------------------------------------------|
| Caps = #diameter_caps{} |
| Pkt = #diameter_packet{} |
| ResultCode = integer() |
| CB = eval() |

An incoming CER has been answered with the indicated result code, or discarded. `Caps` contains pairs of values, for the local node and remote peer respectively. `Pkt` contains the CER in question. In the case of rejection by a capabilities callback, the tuple contains the rejecting callback.

{'CER', Caps, {ResultCode, Pkt}}

| ResultCode = integer() |
| Caps = #diameter_caps{} |
| Pkt = #diameter_packet{} |

An incoming CER contained errors and has been answered with the indicated result code. `Caps` contains values for the local node only. `Pkt` contains the CER in question.

{'CER', timeout}

An expected CER was not received within `capx_timeout` of connection establishment.

{'CEA', Result, Caps, Pkt}

| Result = ResultCode | atom() | {capabilities_cb, CB, ResultCode|discard} |
|----------------------|--------|-------------------------------------------|
| Caps = #diameter_caps{} |
| Pkt = #diameter_packet{} |
| ResultCode = integer() |

An incoming CEA has been rejected for the indicated reason. An integer-valued `Result` indicates the result code sent by the peer. `Caps` contains pairs of values for the local node and remote peer. `Pkt` contains the CEA in question. In the case of rejection by a capabilities callback, the tuple contains the rejecting callback.

{'CEA', Caps, Pkt}

| Caps = #diameter_caps{} |
| Pkt = #diameter_packet{} |
An incoming CEA contained errors and has been rejected. Caps contains only values for the local node. Pkt contains the CEA in question.

{'CEA', timeout}

An expected CEA was not received within capx_timeout of connection establishment.

{watchdog, Ref, PeerRef, {From, To}, Config}

Ref = transport_ref()
PeerRef = diameter_app:peer_ref()
From, To = initial | okay | suspect | down | reopen
Config = {connect|listen, [transport_opt()]} An RFC 3539 watchdog state machine has changed state.

any()

For forward compatibility, a subscriber should be prepared to receive info fields of forms other than the above.

service_name() = term()

Name of a service as passed to start_service/2 and with which the service is identified. There can be at most one service with a given name on a given node. Note that erlang:make_ref/0 can be used to generate a service name that is somewhat unique.

service_opt()

Option passed to start_service/2. Can be any capability() as well as the following.

{application, [application_opt()]} A Diameter application supported by the service.

A service must configure one tuple for each Diameter application it intends to support. For an outgoing request, the relevant application_alias() is passed to call/4, while for an incoming request the application identifier in the message header determines the application, the identifier being specified in the application's dictionary file.

**Warning:**

The capabilities advertised by a node must match its configured applications. In particular, application configuration must be matched by corresponding capability() configuration, of *-Application-Id AVPs in particular.

{decode_format, record | list | map | none}

The format of decoded messages and grouped AVPs in the msg field of diameter_packet records and value field of diameter_avp records respectively. If record then a record whose definition is generated from the dictionary file in question. If list or map then a [Name | Avps] pair where Avps is a list of AVP name/values pairs or a map keyed on AVP names respectively. If none then the atom-value message name, or undefined for a Grouped AVP. See also diameter_codec:message().

Defaults to record.

**Note:**

AVPs are decoded into a list of diameter_avp records in avps field of diameter_packet records independently of decode_format.
{restrict_connections, false | node | nodes | [node()] | eval()}

The degree to which the service allows multiple transport connections to the same peer, as identified by its Origin-Host at capabilities exchange.

If [node()] then a connection is rejected if another already exists on any of the specified nodes. Types false, node, nodes and eval() are equivalent to [], [node()], [node()]|nodes() and the evaluated value respectively, evaluation of each expression taking place whenever a new connection is to be established. Note that false allows an unlimited number of connections to be established with the same peer.

Multiple connections are independent and governed by their own peer and watchdog state machines.

Defaults to nodes.

{sequence, {H,N} | eval()}

A constant value \( H \) for the topmost \( 32-N \) bits of of 32-bit End-to-End and Hop-by-Hop Identifiers generated by the service, either explicitly or as a return value of a function to be evaluated at start_service/2. In particular, an identifier \( Id \) is mapped to a new identifier as follows.

\[
(H \text{ bsl } N) \text{ bor } (Id \text{ band } ((1 \text{ bsl } N) - 1))
\]

Note that RFC 6733 requires that End-to-End Identifiers remain unique for a period of at least 4 minutes and that this and the call rate places a lower bound on appropriate values of \( N \): at a rate of \( R \) requests per second, an \( N \)-bit counter traverses all of its values in \( (1 \text{ bsl } N) \text{ div } (R*60) \) minutes, so the bound is \( 4*R*60 =< 1 \text{ bsl } N \).

\( N \) must lie in the range \( 0..32 \) and \( H \) must be a non-negative integer less than \( 1 \text{ bsl } (32-N) \).

Defaults to \( \{0,32\} \).

**Warning:**

Multiple Erlang nodes implementing the same Diameter node should be configured with different sequence masks to ensure that each node uses a unique range of End-to-End and Hop-by-Hop Identifiers for outgoing requests.

{share_peers, boolean() | [node()] | eval()}

Nodes to which peer connections established on the local Erlang node are communicated. Shared peers become available in the remote candidates list passed to pick_peer/4 callbacks on remote nodes whose services are configured to use them: see use_shared_peers below.

If false then peers are not shared. If [node()] then peers are shared with the specified list of nodes. If eval() then peers are shared with the nodes returned by the specified function, evaluated whenever a peer connection becomes available or a remote service requests information about local connections. The value true is equivalent to fun erlang:nodes/0. The value node() in a list is ignored, so a collection of services can all be configured to share with the same list of nodes.

Defaults to false.
Note:
Peers are only shared with services of the same name for the purpose of sending outgoing requests. Since
the value of the application_opt() alias, passed to call/4, is the handle for identifying a peer as a suitable
candidate, services that share peers must use the same aliases to identify their supported applications.
They should typically also configure identical capabilities(), since by sharing peer connections they are
distributing the implementation of a single Diameter node across multiple Erlang nodes.

{strict_arities, boolean() | encode | decode}
Whether or not to require that the number of AVPs in a message or grouped AVP agree with those specified
in the dictionary in question when passing messages to diameter_app(3) callbacks. If true then mismatches
in an outgoing messages cause message encoding to fail, while mismatches in an incoming message are
reported as 5005/5009 errors in the errors field of the diameter_packet record passed to handle_request/3 or
handle_answer/4 callbacks. If false then neither error is enforced/detected. If encode or decode then
errors are only enforced/detected on outgoing or incoming messages respectively.
Defaults to true.

Note:
Disabling arity checks affects the form of messages at encode/decode. In particular, decoded AVPs are
represented as lists of values, regardless of the AVP’s arity (ie. expected number in the message/AVP
grammar in question), and values are expected to be supplied as lists at encode. This differs from the
historic decode behaviour of representing AVPs of arity 1 as bare values, not wrapped in a list.

{string_decode, boolean()}
Whether or not to decode AVPs of type OctetString() and its derived types DiameterIdentity(),
DiameterURI(), IPFilterRule(), QoSFilterRule(), and UTF8String(). If true then AVPs of these types are
decoded to string(). If false then values are retained as binary().
Defaults to true.

Warning:
This option should be set to false since a sufficiently malicious peer can otherwise cause large amounts
of memory to be consumed when decoded Diameter messages are passed between processes. The default
value is for backwards compatibility.

{traffic_counters, boolean()}
Whether or not to count application-specific messages; those for which diameter_app(3) callbacks take
place. If false then only messages handled by diameter itself are counted: CER/CEA, DWR/DWA, DPR/
DPA.
Defaults to true.

Note:
Disabling counters is a performance improvement, but means that the omitted counters are not returned
by service_info/2.
Nodes from which communicated peers are made available in the remote candidates list of `pick_peer/4` callbacks.

If `false` then remote peers are not used. If `[node()]` then only peers from the specified list of nodes are used. If `eval()` then only peers returned by the specified function are used, evaluated whenever a remote service communicates information about an available peer connection. The value `true` is equivalent to `fun erlang: nodes/0`. The value `node()` in a list is ignored.

Defaults to `false`.

### Note:

A service that does not use shared peers will always pass the empty list as the second argument of `pick_peer/4` callbacks.

### Warning:

Sending a request over a peer connection on a remote node is less efficient than sending it over a local connection. It may be preferable to make use of the `service_opt()` `restrict_connections` and maintain a dedicated connection on each node from which requests are sent.

### transport_opt() 

Any transport option except `applications` or `capabilities`. Used as defaults for transport configuration, values passed to `add_transport/2` overriding values configured on the service.

### transport_opt() 

Option passed to `add_transport/2`. Has one of the following types.

### {applications, [application_alias()]} 

Diameter applications to which the transport should be restricted. Defaults to all applications configured on the service in question. Applications not configured on the service in question are ignored.

### Warning:

The capabilities advertised by a node must match its configured applications. In particular, setting `applications` on a transport typically implies having to set matching `-Application-Id` AVPs in a `capabilities()` tuple.

### {avp_dictionaries, [module()]} 

A list of alternate dictionary modules with which to encode/decode AVPs that are not defined by the dictionary of the application in question. At decode, such AVPs are represented as `diameter_avp` records in the `AVP` field of a decoded message or Grouped AVP, the first alternate that succeeds in decoding the AVP setting the record's value field. At encode, values in an `AVP` list can be passed as AVP name/value 2-tuples, and it is an encode error for no alternate to define the AVP of such a tuple.

Defaults to the empty list.
Note:
The motivation for alternate dictionaries is RFC 7683, Diameter Overload Indication Conveyance (DOIC), which defines AVPs to be piggybacked onto existing application messages rather than defining an application of its own. The DOIC dictionary is provided by the diameter application, as module `diameter_gen_doic_rfc7683`, but alternate dictionaries can be used to encode/decode any set of AVPs not known to an application dictionary.

```
{capabilities, [capability()]}
```

AVPs used to construct outgoing CER/CEA messages. Values take precedence over any specified on the service in question.

Specifying a capability as a transport option may be particularly appropriate for Inband-Security-Id, in case TLS is desired over TCP as implemented by `diameter_tcp(3)`.

```
{capabilities_cb, eval()}
```

Callback invoked upon reception of CER/CEA during capabilities exchange in order to ask whether or not the connection should be accepted. Applied to the `transport_ref()` and `#diameter_caps{}` record of the connection.

The return value can have one of the following types.

- `ok`
  - Accept the connection.
- `integer()`
  - Causes an incoming CER to be answered with the specified Result-Code.
- `discard`
  - Causes an incoming CER to be discarded without CEA being sent.
- `unknown`
  - Equivalent to returning 3010, DIAMETER_UNKNOWN_PEER.

Returning anything but `ok` or a 2xxx series result code causes the transport connection to be broken. Multiple `capabilities_cb` options can be specified, in which case the corresponding callbacks are applied until either all return `ok` or one does not.

```
{capx_timeout, Unsigned32()}
```

Number of milliseconds after which a transport process having an established transport connection will be terminated if the expected capabilities exchange message (CER or CEA) is not received from the peer. For a connecting transport, the timing of connection attempts is governed by `connect_timer` or `watchdog_timer` expiry. For a listening transport, the peer determines the timing.

Defaults to 10000.

```
{connect_timer, Tc}
```

```
Tc = Unsigned32()
```

For a connecting transport, the RFC 6733 Tc timer, in milliseconds. This timer determines the frequency with which a transport attempts to establish an initial connection with its peer following transport configuration. Once an initial connection has been established, `watchdog_timer` determines the frequency of reconnection attempts, as required by RFC 3539.
For a listening transport, the timer specifies the time after which a previously connected peer will be forgotten: a connection after this time is regarded as an initial connection rather than reestablishment, causing the RFC 3539 state machine to pass to state OKAY rather than REOPEN. Note that these semantics are not governed by the RFC and that a listening transport's `connect_timer` should be greater than its peer's Tw plus jitter.

Defaults to 30000 for a connecting transport and 60000 for a listening transport.

```
{disconnect_cb, eval()}
```

Callback invoked prior to terminating the transport process of a transport connection having watchdog state OKAY. Applied to `application|service|transport` and the `transport_ref()` and `diameter_app:peer()` in question: `application` indicates that the diameter application is being stopped, `service` that the service in question is being stopped by `stop_service/1`, and `transport` that the transport in question is being removed by `remove_transport/2`.

The return value can have one of the following types.

```
{dpr, [option()]}
```

Send Disconnect-Peer-Request to the peer, the transport process being terminated following reception of Disconnect-Peer-Answer or timeout. An `option()` can be one of the following.

```
{cause, 0|rebooting|1|busy|2|goaway}
```

Disconnect-Cause to send, REBOOTING, BUSY and DO_NOT_WANT_TO_TALK_TO_YOU respectively. Defaults to `rebooting` for Reason=service|application and `goaway` for Reason=transport.

```
{timeout, Unsigned32()}
```

Number of milliseconds after which the transport process is terminated if DPA has not been received. Defaults to the value of `dpa_timeout`.

```
dpr
```

Equivalent to `{dpr, []}`.

```
close
```

Terminate the transport process without Disconnect-Peer-Request being sent to the peer.

```
ignore
```

Equivalent to not having configured the callback.

Multiple `disconnect_cb` options can be specified, in which case the corresponding callbacks are applied until one of them returns a value other than `ignore`. All callbacks returning `ignore` is equivalent to not having configured them.

Defaults to a single callback returning `dpr`.

```
{dpa_timeout, Unsigned32()}
```

Number of milliseconds after which a transport connection is terminated following an outgoing DPR if DPA is not received.

Defaults to 1000.

```
{dpr_timeout, Unsigned32()}
```

Number of milliseconds after which a transport connection is terminated following an incoming DPR if the peer does not close the connection.

Defaults to 5000.
diameter

{incoming_maxlen, 0..16777215}

Bound on the expected size of incoming Diameter messages. Messages larger than the specified number of bytes are discarded.

Defaults to 16777215, the maximum value of the 24-bit Message Length field in a Diameter Header.

{length_errors, exit|handle|discard}

How to deal with errors in the Message Length field of the Diameter Header in an incoming message. An error in this context is that the length is not at least 20 bytes (the length of a Header), is not a multiple of 4 (a valid length) or is not the length of the message in question, as received over the transport interface documented in diameter_transport(3).

If exit then the transport process in question exits. If handle then the message is processed as usual, a resulting handle_request/3 or handle_answer/4 callback (if one takes place) indicating the 5015 error (DIAMETER_INVALID_MESSAGE_LENGTH). If discard then the message in question is silently discarded.

Defaults to exit.

Note:
The default value reflects the fact that a transport module for a stream-oriented transport like TCP may not be able to recover from a message length error since such a transport must use the Message Length header to divide the incoming byte stream into individual Diameter messages. An invalid length leaves it with no reliable way to rediscover message boundaries, which may result in the failure of subsequent messages. See diameter_tcp(3) for the behaviour of that module.

{pool_size, pos_integer()}

Number of transport processes to start. For a listening transport, determines the size of the pool of accepting transport processes, a larger number being desirable for processing multiple concurrent peer connection attempts. For a connecting transport, determines the number of connections to the peer in question that will be attempted to be established: the service_opt(): restrict_connections should also be configured on the service in question to allow multiple connections to the same peer.

{spawn_opt, [term()] | {M,F,A}}

An options list passed to erlang:spawn_opt/2 to spawn a handler process for an incoming Diameter request on the local node, or an MFA that returns the pid of a handler process.

Options monitor and link are ignored in the list-valued case. An MFA is applied with an additional term prepended to its argument list, and should return either the pid of the handler process that invokes diameter_traffic:request/1 on the term in order to process the request, or the atom discard. The handler process need not be local, but diameter must be started on the remote node.

Defaults to the empty list.

{strict_capx, boolean()}

Whether or not to enforce the RFC 6733 requirement that any message before capabilities exchange should close the peer connection. If false then unexpected messages are discarded.

Defaults to true. Changing this results in non-standard behaviour, but can be useful in case peers are known to be behave badly.

{strict_mbit, boolean()}

Whether or not to regard an AVP setting the M-bit as erroneous when the command grammar in question does not explicitly allow the AVP. If true then such AVPs are regarded as 5001 errors,
DIAMETER_AVP_UNSUPPORTED. If false then the M-bit is ignored and policing it becomes the receiver's responsibility.

Defaults to true.

**Warning:**

RFC 6733 is unclear about the semantics of the M-bit. One the one hand, the CCF specification in section 3.2 documents AVP in a command grammar as meaning any arbitrary AVP; on the other hand, 1.3.4 states that AVPs setting the M-bit cannot be added to an existing command: the modified command must instead be placed in a new Diameter application.

The reason for the latter is presumably interoperability: allowing arbitrary AVPs setting the M-bit in a command makes its interpretation implementation-dependent, since there's no guarantee that all implementations will understand the same set of arbitrary AVPs in the context of a given command. However, interpreting AVP in a command grammar as any AVP, regardless of M-bit, renders 1.3.4 meaningless, since the receiver can simply ignore any AVP it thinks isn't relevant, regardless of the sender's intent.

Beware of confusing mandatory in the sense of the M-bit with mandatory in the sense of the command grammar. The former is a semantic requirement: that the receiver understand the semantics of the AVP in the context in question. The latter is a syntactic requirement: whether or not the AVP must occur in the message in question.

```
{transport_config, term()}
{transport_config, term(), Unsigned32() | infinity}
```

Term passed as the third argument to the start/3 function of the relevant transport module in order to start a transport process. Defaults to the empty list.

The 3-tuple form additionally specifies an interval, in milliseconds, after which a started transport process should be terminated if it has not yet established a connection. For example, the following options on a connecting transport request a connection with one peer over SCTP or another (typically the same) over TCP.

```
{transport_module, diameter_sctp}
{transport_config, SctpOpts, 5000}
{transport_module, diameter_tcp}
{transport_config, TcpOpts}
```

To listen on both SCTP and TCP, define one transport for each.

```
{transport_module, atom()}
```

Module implementing a transport process as defined in diameter_transport(3). Defaults to diameter_tcp.

Multiple transport_module and transport_config options are allowed. The order of these is significant in this case (and only in this case), a transport_module being paired with the first transport_config following it in the options list, or the default value for trailing modules. Transport starts will be attempted with each of the modules in order until one establishes a connection within the corresponding timeout (see below) or all fail.

```
{watchdog_config, [{okay|suspect, non_neg_integer()}]}
```

Configuration that alters the behaviour of the watchdog state machine. On key okay, the non-negative number of answered DWR messages before transitioning from REOPEN to OKAY. On key suspect, the number of watchdog timeouts before transitioning from OKAY to SUSPECT when DWR is unanswered, or 0 to not make the transition.
Defaults to \[
\{\text{okay, 3}\}, \{\text{suspect, 1}\}\]. Not specifying a key is equivalent to specifying the default value for that key.

**Warning:**

The default value is as required by RFC 3539: changing it results in non-standard behaviour that should only be used to simulate misbehaving nodes during test.

{\text{watchdog\_timer, TwInit}}

\[
\text{TwInit} = \text{Unsigned32()} \\
| \{M,F,A\}
\]

The RFC 3539 watchdog timer. An integer value is interpreted as the RFC’s TwInit in milliseconds, a jitter of ± 2 seconds being added at each rearming of the timer to compute the RFC’s Tw. An MFA is expected to return the RFC’s Tw directly, with jitter applied, allowing the jitter calculation to be performed by the callback.

An integer value must be at least 6000 as required by RFC 3539. Defaults to 30000.

Unrecognized options are silently ignored but are returned unmodified by \text{service\_info/2} and can be referred to in predicate functions passed to \text{remove\_transport/2}.

\text{transport\_ref()} = \text{reference()}

Reference returned by \text{add\_transport/2} that identifies the configuration.

**Exports**

\text{add\_transport(SvcName, \{connect|listen, [Opt]\})} \to \{\text{ok, Ref}\} | \{\text{error, Reason}\}

Types:

\[
\begin{align*}
\text{SvcName} &= \text{service\_name()} \\
\text{Opt} &= \text{transport\_opt()} \\
\text{Ref} &= \text{transport\_ref()} \\
\text{Reason} &= \text{term()}
\end{align*}
\]

Add transport capability to a service.

The service will start transport processes as required in order to establish a connection with the peer, either by connecting to the peer (connect) or by accepting incoming connection requests (listen). A connecting transport establishes transport connections with at most one peer, an listening transport potentially with many.

The diameter application takes responsibility for exchanging CER/CEA with the peer. Upon successful completion of capabilities exchange the service calls each relevant application module’s \text{peer\_up/3} callback after which the caller can exchange Diameter messages with the peer over the transport. In addition to CER/CEA, the service takes responsibility for the handling of DWR/DWA and required by RFC 3539, as well as for DPR/DPA.

The returned reference uniquely identifies the transport within the scope of the service. Note that the function returns before a transport connection has been established.

**Note:**

It is not an error to add a transport to a service that has not yet been configured: a service can be started after configuring its transports.
call(SvcName, App, Request, [Opt]) -> Answer | ok | {error, Reason}
Types:
  SvcName = service_name()
  App = application_alias()
  Request = diameter_codec:message()
  Answer = term()
  Opt = call_opt()
Send a Diameter request message.

App specifies the Diameter application in which the request is defined and callbacks to the corresponding callback module will follow as described below and in \texttt{diameter_app(3)}. Unless the 	exttt{detach} option is specified, the call returns either when an answer message is received from the peer or an error occurs. In the answer case, the return value is as returned by a \texttt{handle_answer/4} callback. In the error case, whether or not the error is returned directly by diameter or from a \texttt{handle_error/4} callback depends on whether or not the outgoing request is successfully encoded for transmission to the peer, the cases being documented below.

If there are no suitable peers, or if \texttt{pick_peer/4} rejects them by returning \texttt{false}, then \texttt{{error,no_connection}} is returned. Otherwise \texttt{pick_peer/4} is followed by a \texttt{prepare_request/3} callback, the message is encoded and then sent.

There are several error cases which may prevent an answer from being received and passed to a \texttt{handle_answer/4} callback:

- If the initial encode of the outgoing request fails, then the request process fails and \texttt{{error,encode}} is returned.
- If the request is successfully encoded and sent but the answer times out then a \texttt{handle_error/4} callback takes place with \texttt{Reason = timeout}.
- If the request is successfully encoded and sent but the service in question is stopped before an answer is received then a \texttt{handle_error/4} callback takes place with \texttt{Reason = cancel}.
- If the transport connection with the peer goes down after the request has been sent but before an answer has been received then an attempt is made to resend the request to an alternate peer. If no such peer is available, or if the subsequent \texttt{pick_peer/4} callback rejects the candidates, then a \texttt{handle_error/4} callback takes place with \texttt{Reason = failover}. If a peer is selected then a \texttt{prepare_retransmit/3} callback takes place, after which the semantics are the same as following an initial \texttt{prepare_request/3} callback.
- If an encode error takes place during retransmission then the request process fails and \texttt{{error,failure}} is returned.
- If an application callback made in processing the request fails (\texttt{pick_peer}, \texttt{prepare_request}, \texttt{prepare_retransmit}, \texttt{handle_answer} or \texttt{handle_error}) then either \texttt{{error,encode}} or \texttt{{error,failure}} is returned depending on whether or not there has been an attempt to send the request over the transport.

Note that \texttt{{error,encode}} is the only return value which guarantees that the request has not been sent over the transport connection.

\texttt{origin_state_id()} -> Unsigned32()

Return a reasonable value for use as Origin-State-Id in outgoing messages.

The value returned is the number of seconds since 19680120T031408Z, the first value that can be encoded as a Diameter Time(), at the time the diameter application was started.

\texttt{remove_transport(SvcName, Pred) -> ok | {error, Reason}}
Types:
  SvcName = service_name()
Remove previously added transports.

Pred determines which transports to remove. An arity-3-valued Pred removes all transports for which Pred(Ref, Type, Opts) returns true, where Type and Opts are as passed to add_transport/2 and Ref is as returned by it. The remaining forms are equivalent to an arity-3 fun as follows.

```
Pred = fun(transport_ref(), list()):  fun(Ref, _, Opts) -> Pred(Ref, Opts) end
Pred = fun(list()):                   fun(_, _, Opts) -> Pred(Opts) end
Pred = transport_ref():               fun(Ref, _, _)  -> Pred == Ref end
Pred = list():                        fun(_, _, Opts) -> [] == Pred ++ Opts end
Pred = true:                          fun(_, _, _) -> true end
Pred = false:                         fun(_, _, _) -> false end
Pred = {M,F,A}:  fun(Ref, Type, Opts) -> apply(M, F, [Ref, Type, Opts | A]) end
```

Removing a transport causes the corresponding transport processes to be terminated. Whether or not a DPR message is sent to a peer is controlled by value of disconnect_cb configured on the transport.

```
service_info(SvcName, Info) -> term()
```

Types:

- **SvcName** = service_name()
- **Info** = Item | [Info]
- **Item** = atom()

Return information about a started service. Requesting info for an unknown service causes undefined to be returned. Requesting a list of items causes a tagged list to be returned.

Item can be one of the following.

- 'Origin-Host'
- 'Origin-Realm'
- 'Vendor-Id'
- 'Product-Name'
- 'Origin-State-Id'
- 'Host-IP-Address'
- 'Supported-Vendor'
- 'Auth-Application-Id'
- 'Inband-Security-Id'
- 'Acct-Application-Id'
- 'Vendor-Specific-Application-Id'
- 'Firmware-Revision'

Return a capability value as configured with start_service/2.

```
applications
```

Return the list of applications as configured with start_service/2.

```
capabilities
```

Return a tagged list of all capabilities values as configured with start_service/2.
transport

Return a list containing one entry for each of the service’s transport as configured with add_transport/2. Each entry is a tagged list containing both configuration and information about established peer connections. An example return value with for a client service with Origin-Host "client.example.com" configured with a single transport connected to "server.example.com" might look as follows.

```
[[{ref,#Ref<0.0.0.93>},
  {type,connect},
  {options,[[{transport_module,diameter_tcp},
    {transport_config,[[{ip,[127,0,0,1]},
      {raddr,[127,0,0,1]},
      {rport,3868},
      {reuseaddr,true}]}
    ]},
  {watchdog,{{<0.66.0>,-576460736368485571,okay}},
  {peer,{{<0.67.0>,-576460736357885808}},
  {apps,[[0,common]]},
  {caps,[[{origin_host,{"client.example.com","server.example.com"}},
    {origin_realm,{"example.com","example.com"}},
    {host_ip_address,[[[127,0,0,1]],[[127,0,0,1]]]},
    {vendor_id,[0,193]},
    {product_name,"Client","Server"},
    {origin_state_id,[]},
    {supported_vendor_id,[]},
    {auth_application_id,[0,0]},
    {inband_security_id,[]},
    {acct_application_id,[]},
    {vendor_specific_application_id,[]},
    {firmware_revision,[]},
    {avp,[]}],
  {port,[[{owner,<0.69.0>},
    {module,diameter_tcp},
    {socket,[[127,0,0,1],48758]},
    {peer,[[127,0,0,1],3868]},
    {statistics,[[recv_oct,656],
      {recv_cnt,6},
      {recv_max,148},
      {recv_avg,109},
      {recv_dvi,19},
      {send_oct,836},
      {send_cnt,6},
      {send_max,184},
      {send_avg,139},
      {send_pend,0}]},
    {statistics,[[{{0,258,0},recv},3],
      {{0,258,0},send},3],
      {{0,258,0},recv,{'Result-Code',2001}},3],
      {{0,257,0},recv},1],
    {{0,257,1},send},1],
    {{0,257,0},recv,{'Result-Code',2001}},1],
    {{0,280,1},recv},2],
    {{0,280,0},send},2],
    {{0,280,0},send,{'Result-Code',2001}},2]]}]]
```

Here ref is a transport_ref() and options the corresponding transport_opt() list passed to add_transport/2. The watchdog entry shows the state of a connection’s RFC 3539 watchdog state machine. The peer entry identifies the diameter_app:peer_ref() for which there will have been peer_up/3 callbacks for the Diameter applications identified by the apps entry, common being the application_alias(). The caps entry identifies the capabilities sent by the local node and received from the peer during capabilities exchange. The port entry displays socket-level information about the transport connection. The statistics
entry presents Diameter-level counters, an entry like \{{{0,280,1},recv},2\} saying that the client has received 2 DWR messages: \{(Application_Id, Command_Code, R_Flag)\}.

Note that watchdog, peer, apps, caps and port entries depend on connectivity with the peer and may not be present. Note also that the statistics entry presents values accumulated during the lifetime of the transport configuration.

A listening transport presents its information slightly differently since there may be multiple accepted connections for the same transport_ref(). The transport info returned by a server with a single client connection might look as follows.

\[
\begin{align*}
&[[\text{ref}, \text{#Ref<0.0.0.61>>}, \text{type}, \text{listen}], \text{options,}[[\text{transport_module, diameter_tcp}], \text{transport_config,}[[\text{reuseaddr, true}], \text{ip,}[[127,0,0,1]], \text{port,}3868]])], \text{accept,}[[\text{watchdog,}(<0.56.0>,-576460739249514012,okay>), \text{peer,}(<0.58.0>,-576460638229179167>), \text{apps,}[[0, common]]], \text{caps,}[[\text{origin_host,}"\text{server.example.com", "client.example.com"}], \text{origin Realm,}"\text{example.com", "example.com"}], \text{host_ip_address,}[[127,0,0,1],[127,0,0,1]]], \text{vendor_id,}193], \text{product_name,}"\text{Server", "Client"}], \text{origin_state_id,}[[],[]], \text{supported_vendor_id,}[[],[]], \text{auth_application_id,}[[0],[0]], \text{inband_security_id,}[[],[]], \text{acct_application_id,}[[],[]], \text{vendor_specific_application_id,}[[],[]], \text{firmware_revision,}[[],[]], \text{avp,}[[],[]]], \text{port,}[[\text{owner,}(<0.62.0>), \text{module,diameter_tcp}], \text{socket,}[[127,0,0,1],3868>], \text{peer,}[[127,0,0,1],48758>], \text{statistics,}[[\text{recv_oct,}1576], \text{recv_cnt,}16], \text{recv_max,}184], \text{recv_avg,}98], \text{recv_dvi,}26], \text{send_oct,}1396], \text{send_cnt,}16], \text{send_max,}148], \text{send_avg,}87], \text{send_pend,}0]], \text{watchdog,}(<0.72.0>,-576460638229717546,initial>)]], \text{statistics,}[[[0,280,0],recv],7], [[0,280,1],send],7], [[0,280,0],recv,\{\text{Result-Code',}2001\}],7], [[0,258,1],recv],3], [[0,258,0],send],3], [[0,258,0],send,\{\text{Result-Code',}2001\}],3], [[0,280,1],recv],5], [[0,280,0],send],5], [[0,280,0],send,\{\text{Result-Code',}2001\}],5], [[0,257,1],recv],1], [[0,257,0],send],1], [[0,257,0],send,\{\text{Result-Code',}2001\}],1]]]]
\end{align*}
\]

The information presented here is as in the connect case except that the client connections are grouped under an accept tuple.
Whether or not the transport_opt() pool_size has been configured affects the format of the listing in the case of a connecting transport, since a value greater than 1 implies multiple transport processes for the same transport_ref(), as in the listening case. The format in this case is similar to the listening case, with a pool tuple in place of an accept tuple.

connections

Return a list containing one entry for every established transport connection whose watchdog state machine is not in the down state. This is a flat view of transport info which lists only active connections and for which Diameter-level statistics are accumulated only for the lifetime of the transport connection. A return value for the server above might look as follows.

```plaintext
[[{ref,#Ref<0.0.0.61>},
  {type,accept},
  {options,[[transport_module,diameter_tcp],
    {transport_config,[[reuseaddr,true],
      {ip,[{127,0,0,1}],
        {port,3868}]},
    {pool_size,12}]]},
  {watchdog,<{<0.56.0>,-576460739249514012,okay}>,
   {peer,<{<0.58.0>,-576460638229179167}>,
    {apps,[[0,common]]},
    {caps,[[origin_host,"server.example.com","client.example.com"],
      {origin_real,"example.com","example.com"},
      {host_ip_address,[[127,0,0,1],[127,0,0,1]]},
      {vendor_id,193},
      {product_name,"Server","Client"},
      {origin_state_id,[]},
      {supported_vendor_id,[]},
      {inband_security_id,[]},
      {acct_application_id,[]},
      {vendor_specific_application_id,[]},
      {firmware_revision,[]},
      {app,[]}]},
   {port,{{owner,<0.62.0>},
     {module,diameter_tcp},
     {socket,[[127,0,0,1],3868]],
     {peer,[[127,0,0,1],48758]}},
    {statistics,[[recv_oct,10124],
      {recv_cnt,132},
      {recv_max,184},
      {recv_avg,76},
      {recv_dvi,9},
      {send_oct,10016},
      {send_cnt,132},
      {send_max,148},
      {send_avg,75},
      {send_pend,0}]],
     {statistics,[[{{0,280,0},recv},62],
      {{{0,280,1},send},62},
      {{{0,258,0},recv},3},
      {{{0,258,1},send},3},
      {{{0,280,0},recv},66},
      {{{0,280,1},send},66},
      {{{0,280,0},send},66},
      {{{0,280,0},recv},66},
      {{{0,257,1},recv},1},
      {{{0,257,0},send},1},
      {{{0,257,0},recv},1}]],
    {statistics,[]}}]
```

Note that there may be multiple entries with the same ref, in contrast to transport info.
statistics

Return a \{(Counter, Ref), non_neg_integer()\} list of counter values. Ref can be either a transport_ref() or a diameter_app:peer_ref(). Entries for the latter are folded into corresponding entries for the former as peer connections go down. Entries for both are removed at remove_transport/2. The Diameter-level statistics returned by transport and connections info are based upon these entries.

diameter_app:peer_ref()

Return transport configuration associated with a single peer, as passed to add_transport/2. The returned list is empty if the peer is unknown. Otherwise it contains the ref, type and options tuples as in transport and connections info above. For example:

```
[\{ref, #Ref<0.0.0.61>\},
 \{type, accept\},
 \{options, [[transport_module, diameter_tcp],
     \{transport_config, [[reuseaddr, true],
       \{ip, [127,0,0,1]},
       \{port, 3868}\]}}]
```

services() -> [SvcName]

Types:

\[SvcName = service_name()\]

Return the list of started services.

session_id(Ident) -> OctetString()

Types:

\[Ident = DiameterIdentity()\]

Return a value for a Session-Id AVP.

The value has the form required by section 8.8 of RFC 6733. Ident should be the Origin-Host of the peer from which the message containing the returned value will be sent.

start() -> ok | {error, Reason}

Start the diameter application.

The diameter application must be started before starting a service. In a production system this is typically accomplished by a boot file, not by calling start/0 explicitly.

start_service(SvcName, Options) -> ok | {error, Reason}

Types:

\[SvcName = service_name()
Options = [service_opt()]
Reason = term()\]

Start a diameter service.

A service defines a locally-implemented Diameter node, specifying the capabilities to be advertised during capabilities exchange. Transports are added to a service using add_transport/2.
stop() -> ok | {error, Reason}
Stop the diameter application.

stop_service(SvcName) -> ok | {error, Reason}
Types:
  SvcName = service_name()
  Reason = term()
Stop a diameter service.
Stopping a service causes all associated transport connections to be broken. A DPR message will be sent as in the case of remove_transport/2.

Note:
Stopping a service does not remove any associated transports: remove_transport/2 must be called to remove transport configuration.

subscribe(SvcName) -> true
Types:
  SvcName = service_name()
Subscribe to service_event() messages from a service.
It is not an error to subscribe to events from a service that does not yet exist. Doing so before adding transports is required to guarantee the reception of all transport-related events.

unsubscribe(SvcName) -> true
Types:
  SvcName = service_name()
Unsubscribe to event messages from a service.

SEE ALSO
diameter_app(3), diameter_transport(3), diameter_dict(4)
The diameterc utility is used to compile a diameter dictionary file into Erlang source. The resulting source implements the interface diameter required to encode and decode the dictionary's messages and AVPs.

The module `diameter_make(3)` provides an alternate compilation interface.

**USAGE**

diameterc [ <options> ] <file>

  Compile a single dictionary file to Erlang source. Valid options are as follows.
  - `-i <dir>`
    Prepend the specified directory to the code path. Use to point at beam files compiled from inherited dictionaries, `@inherits` in a dictionary file creating a beam dependency, not an erl/hrl dependency.
    Multiple `-i` options can be specified.
  - `-o <dir>`
    Write generated source to the specified directory. Defaults to the current working directory.
  - `-E`
    -H
    Suppress erl and hrl generation, respectively.
  - `--name <name>`
  - `--prefix <prefix>`
    Transform the input dictionary before compilation, setting `@name` or `@prefix` to the specified string.
  - `--inherits <arg>`
    Transform the input dictionary before compilation, appending `@inherits` of the specified string.
    Two forms of `--inherits` have special meaning:
      - `--inherits Prev/Mod`
        The first has the effect of clearing any previous inherits, the second of replacing a previous inherits of `Prev` to one of `Mod`. This allows the semantics of the input dictionary to be changed without modifying the file itself.
        Multiple `--inherits` options can be specified.

**EXIT STATUS**

Returns 0 on success, non-zero on failure.

**SEE ALSO**

`diameter_make(3), diameter_dict(4)`
diameter_app

Erlang module

A diameter service as started by `diameter:start_service/2` configures one of more Diameter applications, each of whose configuration specifies a callback that handles messages specific to the application. The messages and AVPs of the application are defined in a dictionary file whose format is documented in `diameter_dict(4)` while the callback module is documented here. The callback module implements the Diameter application-specific functionality of a service.

A callback module must export all of the functions documented below. The functions themselves are of three distinct flavours:

- `peer_up/3` and `peer_down/3` signal the attainment or loss of connectivity with a Diameter peer.
- `pick_peer/4`, `prepare_request/3`, `prepare_retransmit/3`, `handle_answer/4` and `handle_error/4` are (or may be) called as a consequence of a call to `diameter:call/4` to send an outgoing Diameter request message.
- `handle_request/3` is called in response to an incoming Diameter request message.

The arities for the the callback functions here assume no extra arguments. All functions will also be passed any extra arguments configured with the callback module itself when calling `diameter:start_service/2` and, for the call-specific callbacks, any extra arguments passed to `diameter:call/4`.

**DATA TYPES**

`capabilities() = #diameter_caps{}`

A record containing the identities of the local Diameter node and the remote Diameter peer having an established transport connection, as well as the capabilities as determined by capabilities exchange. Each field of the record is a 2-tuple consisting of values for the (local) host and (remote) peer. Optional or possibly multiple values are encoded as lists of values, mandatory values as the bare value.

`message() = diameter_codec:message()`

The representation of a Diameter message as passed to `diameter:call/4` or returned from a `handle_request/3` callback.

`packet() = diameter_codec:packet()`

A container for incoming and outgoing Diameter messages that’s passed through encode/decode and transport. Fields should not be set in return values except as documented.

`peer_ref() = term()`

A term identifying a transport connection with a Diameter peer.

`peer() = {peer_ref(), capabilities()}`

A tuple representing a Diameter peer connection.

`state() = term()`

The state maintained by the application callback functions `peer_up/3`, `peer_down/3` and (optionally) `pick_peer/4`. The initial state is configured in the call to `diameter:start_service/2` that configures the application on a service. Callback functions returning a state are evaluated in a common service-specific process while those not returning state are evaluated in a request-specific process.
Exports

\textbf{Mod:peer\_up(SvcName, Peer, State) -> NewState}

Types:
\begin{itemize}
  \item \texttt{SvcName} = \textit{diameter:service\_name()}
  \item \texttt{Peer} = \textit{peer()}
  \item \texttt{State} = \texttt{NewState} = \textit{state()}
\end{itemize}

Invoked to signal the availability of a peer connection on the local Erlang node. In particular, capabilities exchange with the peer has indicated support for the application in question, the RFC 3539 watchdog state machine for the connection has reached state \texttt{OKAY} and Diameter messages can be both sent and received.

\textbf{Note:}

A watchdog state machine can reach state \texttt{OKAY} from state \texttt{SUSPECT} without a new capabilities exchange taking place. A new transport connection (and capabilities exchange) results in a new \texttt{peer\_ref()}. 

\textbf{Note:}

There is no requirement that a callback return before incoming requests are received: \textit{handle\_request/3} callbacks must be handled independently of \texttt{peer\_up/3} and \texttt{peer\_down/3}.

\textbf{Mod:peer\_down(SvcName, Peer, State) -> NewState}

Types:
\begin{itemize}
  \item \texttt{SvcName} = \textit{diameter:service\_name()}
  \item \texttt{Peer} = \textit{peer()}
  \item \texttt{State} = \texttt{NewState} = \textit{state()}
\end{itemize}

Invoked to signal that a peer connection on the local Erlang node is no longer available following a previous call to \texttt{peer\_up/3}. In particular, that the RFC 3539 watchdog state machine for the connection has left state \texttt{OKAY} and the peer will no longer be a candidate in \texttt{pick\_peer/4} callbacks.

\textbf{Mod:pick\_peer(LocalCandidates, RemoteCandidates, SvcName, State) -> Selection | false}

Types:
\begin{itemize}
  \item \texttt{LocalCandidates} = \texttt{RemoteCandidates} = \texttt{[peer()]} 
  \item \texttt{SvcName} = \textit{diameter:service\_name()}
  \item \texttt{State} = \texttt{NewState} = \textit{state()}
  \item \texttt{Selection} = \{\texttt{ok, Peer}\} | \{\texttt{Peer, NewState}\}
  \item \texttt{Peer} = \textit{peer()} | \texttt{false}
\end{itemize}

Invoked as a consequence of a call to \textit{diameter:call/4} to select a destination peer for an outgoing request. The return value indicates the selected peer.

The candidate lists contain only those peers that have advertised support for the Diameter application in question during capabilities exchange, that have not be excluded by a \texttt{filter} option in the call to \textit{diameter:call/4} and whose watchdog state machine is in the \texttt{OKAY} state. The order of the elements is unspecified except that any peers whose Origin-Host and Origin-Realm matches that of the outgoing request (in the sense of a \{\texttt{filter, \{all, \{host, realm\}\}}\} option to \textit{diameter:call/4}) will be placed at the head of the list. \texttt{LocalCandidates} contains peers
whose transport process resides on the local Erlang node while RemoteCandidates contains peers that have been communicated from other nodes by services of the same name.

A callback that returns a peer() will be followed by a prepare_request/3 callback and, if the latter indicates that the request should be sent, by either handle_answer/4 or handle_error/4 depending on whether or not an answer message is received from the peer. If the transport becomes unavailable after prepare_request/3 then a new pick_peer/4 callback may take place to failover to an alternate peer, after which prepare_retransmit/3 takes the place of prepare_request/3 in resending the request. There is no guarantee that a pick_peer/4 callback to select an alternate peer will be followed by any additional callbacks since a retransmission to an alternate peer is abandoned if an answer is received from a previously selected peer.

The return values false and (false, State) (that is, NewState = State) are equivalent, as are (ok, Peer) and (Peer, State).

**Note:**

The `diameter:service_opt()` use_shared_peers determines whether or not a service uses peers shared from other nodes. If not then RemoteCandidates is the empty list.

**Warning:**

The return value (Peer, NewState) is only allowed if the Diameter application in question was configured with the `diameter:application_opt()` {call_mutates_state, true}. Otherwise, the State argument is always the initial value as configured on the application, not any subsequent value returned by a peer_up/3 or peer_down/3 callback.

**Mod:prepare_request(Packet, SvcName, Peer) -> Action**

Types:

- **Packet = packet()**
- **SvcName = diameter:service_name()**
- **Peer = peer()**
- **Action = Send | Discard | {eval_packet, Action, PostF}**
  - **Send = {send, packet() | message()}**
  - **Discard = {discard, Reason} | discard**
  - **PostF = diameter:eval()**

Invoked to return a request for encoding and transport. Allows the sender to use the selected peer’s capabilities to modify the outgoing request. Many implementations may simply want to return {send, Packet}

A returned packet() should set the request to be encoded in its msg field and can set the transport_data field in order to pass information to the transport process. Extra arguments passed to `diameter:call/4` can be used to communicate transport (or any other) data to the callback.

A returned packet() can set the header field to a #diameter_header{} to specify values that should be preserved in the outgoing request, values otherwise being those in the header record contained in Packet. A returned length, cmd_code or application_id is ignored.

A returned PostF will be evaluated on any encoded #diameter_packet{} prior to transmission, the bin field containing the encoded binary. The return value is ignored.

Returning {discard, Reason} causes the request to be aborted and the `diameter:call/4` for which the callback has taken place to return {error, Reason}. Returning discard is equivalent to returning {discard, discarded}.
Mod:prepare_retransmit(Packet, SvcName, Peer) -> Action

Types:

Packet = packet()
SvcName = diameter:service_name()
Peer = peer()
Action = Send | Discard | {eval_packet, Action, PostF}
Send = {send, packet() | message()}
Discard = {discard, Reason} | discard
PostF = diameter:eval()

Invoked to return a request for encoding and retransmission. Has the same role as prepare_request/3 in the case that a peer connection is lost and an alternate peer selected but the argument packet() is as returned by the initial prepare_request/3.

Returning {discard, Reason} causes the request to be aborted and a handle_error/4 callback to take place with Reason as initial argument. Returning discard is equivalent to returning {discard, discarded}.

Mod:handle_answer(Packet, Request, SvcName, Peer) -> Result

Types:

Packet = packet()
Request = message()
SvcName = diameter:service_name()
Peer = peer()
Result = term()

Invoked when an answer message is received from a peer. The return value is returned from diameter:call/4 unless the detach option was specified.

The decoded answer record and undecoded binary are in the msg and bin fields of the argument packet() respectively. Request is the outgoing request message as was returned from prepare_request/3 or prepare_retransmit/3.

For any given call to diameter:call/4 there is at most one handle_answer/4 callback: any duplicate answer (due to retransmission or otherwise) is discarded. Similarly, only one of handle_answer/4 or handle_error/4 is called.

By default, an incoming answer message that cannot be successfully decoded causes the request process to fail, causing diameter:call/4 to return {error, failure} unless the detach option was specified. In particular, there is no handle_error/4 callback in this case. The diameter:application_opt() answer_errors can be set to change this behaviour.

Mod:handle_error(Reason, Request, SvcName, Peer) -> Result

Types:

Reason = timeout | failover | term()
Request = message()
SvcName = diameter:service_name()
Peer = peer()
Result = term()

Invoked when an error occurs before an answer message is received in response to an outgoing request. The return value is returned from diameter:call/4 unless the detach option was specified.
Reason **timeout** indicates that an answer message has not been received within the time specified with the corresponding `diameter:call_opt()`. Reason **failover** indicates that the transport connection to the peer to which the request has been sent has become unavailable and that not alternate peer was not selected.

```erlang
Mod:handle_request(Packet, SvcName, Peer) -> Action

Types:
  Packet = packet()
  SvcName = term()
  Peer = peer()
  Action = Reply | {relay, Opt} | discard | {eval, eval_packet, Action, PostF}
  Reply = {reply, packet() | message()} | {answer_message, 3000..3999} | 5000..5999 | {protocol_error, 3000..3999}
  Opt = diameter:call_opt()
  PostF = diameter:eval()
```

Invoked when a request message is received from a peer. The application in which the callback takes place (that is, the callback module as configured with `diameter:start_service/2`) is determined by the Application Identifier in the header of the incoming request message, the selected module being the one whose corresponding dictionary declares itself as defining either the application in question or the Relay application.

The argument `packet()` has the following signature.

```erlang
#diameter_packet{header = #diameter_header{},
  avps   = [#diameter_avp{}],
  msg    = record() | undefined,
  errors = [Unsigned32() | {Unsigned32(), #diameter_avp{}}],
  bin    = binary(),
  transport_data = term()}
```

The `msg` field will be `undefined` in case the request has been received in the relay application. Otherwise it contains the record representing the request as outlined in `diameter_dict(4)`.

The `errors` field specifies any results codes identifying errors found while decoding the request. This is used to set Result-Code and/or Failed-AVP in a returned answer unless the callback returns a `#diameter_packet{}` whose `errors` field is set to either a non-empty list of its own, in which case this list is used instead, or the atom `false` to disable any setting of Result-Code and Failed-AVP. Note that the errors detected by `diameter` are of the 3xxx and 5xxx series, Protocol Errors and Permanent Failures respectively. The `errors` list is empty if the request has been received in the relay application.

The `transport_data` field contains an arbitrary term passed into `diameter` from the transport module in question, or the atom `undefined` if the transport specified no data. The term is preserved if a `message()` is returned but must be set explicitly in a returned `packet()`.

The semantics of each of the possible return values are as follows.

```erlang
{reply, packet() | message()}
```

Send the specified answer message to the peer. In the case of a `packet()`, the message to be sent must be set in the `msg` field and the `header` field can be set to a `#diameter_header{}` to specify values that should be preserved in the outgoing answer, appropriate values otherwise being set by `diameter`.

```erlang
{answer_message, 3000..3999 | 5000..5999}
```

Send an answer message to the peer containing the specified Result-Code. Equivalent to
where Avps sets the Origin-Host, Origin-Realm, the specified Result-Code and (if the request contained one) Session-Id AVPs, and possibly Failed-AVP as described below.

Returning a value other than 3xxx or 5xxx will cause the request process in question to fail, as will returning a 5xxx value if the peer connection in question has been configured with the RFC 3588 common dictionary `diameter_gen_base_rfc3588`. (Since RFC 3588 only allows 3xxx values in an answer-message.)

When returning 5xxx, Failed-AVP will be populated with the AVP of the first matching Result-Code/AVP pair in the errors field of the argument `packet()`, if found. If this is not appropriate then an answer-message should be constructed explicitly and returned in a reply tuple instead.

{relay, Opts}

Relay a request to another peer in the role of a Diameter relay agent. If a routing loop is detected then the request is answered with 3005 (DIAMETER_LOOP_DETECTED). Otherwise a Route-Record AVP (containing the sending peer's Origin-Host) is added to the request and `pick_peer/4` and subsequent callbacks take place just as if `diameter:call/4` had been called explicitly. The End-to-End Identifier of the incoming request is preserved in the header of the relayed request.

The returned Opts should not specify detach. A subsequent `handle_answer/4` callback for the relayed request must return its first argument, the `packet()` containing the answer message. Note that the extra option can be specified to supply arguments that can distinguish the relay case from others if so desired. Any other return value (for example, from a `handle_error/4` callback) causes the request to be answered with 3002 (DIAMETER_UNABLE_TO_DELIVER).

discard

Discard the request. No answer message is sent to the peer.

{eval, Action, PostF}

Handle the request as if Action has been returned and then evaluate PostF in the request process. The return value is ignored.

{eval_packet, Action, PostF}

Like eval but evaluate PostF on any encoded `#diameter_packet{}` prior to transmission, the bin field containing the encoded binary. The return value is ignored.

(protocol_error, 3000..3999)

Equivalent to (answer_message, 3000..3999).

**Note:**

Requests containing errors may be answered by diameter, without a callback taking place, depending on the value of the `diameter:application_opt()` request_errors.
diameter_codec

Erlang module

Incoming Diameter messages are decoded from binary() before being communicated to diameter_app(3) callbacks. Similarly, outgoing Diameter messages are encoded into binary() before being passed to the appropriate diameter_transport(3) module for transmission. The functions documented here implement the default encode/decode.

Warning:
The diameter user does not need to call functions here explicitly when sending and receiving messages using diameter:call/4 and the callback interface documented in diameter_app(3); diameter itself provides encode/decode as a consequence of configuration passed to diameter:start_service/2, and the results may differ from those returned by the functions documented here, depending on configuration.

The header() and packet() records below are defined in diameter.hrl, which can be included as follows.

```
-include_lib("diameter/include/diameter.hrl").
```

Application-specific records are defined in the hrl files resulting from dictionary file compilation.

**DATA TYPES**

- **uint8()** = 0..255
- **uint24()** = 0..16777215
- **uint32()** = 0..4294967295

8-bit, 24-bit and 32-bit integers occurring in Diameter and AVP headers.

- **avp()** = #diameter_avp{}

The application-neutral representation of an AVP. Primarily intended for use by relay applications that need to handle arbitrary Diameter applications. A service implementing a specific Diameter application (for which it configures a dictionary) can manipulate values of type message() instead.

Fields have the following types.

- **code** = uint32()
- **is_mandatory** = boolean()
- **need_encryption** = boolean()
- **vendor_id** = uint32() | undefined

Values in the AVP header, corresponding to AVP Code, the M flag, P flags and Vendor-ID respectively. A Vendor-ID other than undefined implies a set V flag.

- **data** = iolist()

The data bytes of the AVP.

- **name** = atom()

The name of the AVP as defined in the dictionary file in question, or undefined if the AVP is unknown to the dictionary file in question.
value = term()
The decoded value of an AVP. Will be undefined on decode if the data bytes could not be decoded, the AVP is unknown, or if the decode format is none. The type of a decoded value is as document in diameter_dict(4).

type = atom()
The type of the AVP as specified in the dictionary file in question (or one it inherits). Possible types are undefined and the Diameter types: OctetString, Integer32, Integer64, Unsigned32, Unsigned64, Float32, Float64, Grouped, Enumerated, Address, Time, UTF8String, DiameterIdentity, DiameterURI, IPFilterRule and QoSFilterRule.
dictionary() = module()
The name of a generated dictionary module as generated by diameterc(1) or diameter_make:codec/2. The interface provided by a dictionary module is an implementation detail that may change.

header() = #diameter_header{}
The record representation of the Diameter header. Values in a packet() returned by decode/2 are as extracted from the incoming message. Values set in an packet() passed to encode/2 are preserved in the encoded binary(), with the exception of length, cmd_code and application_id, all of which are determined by the dictionary() in question.

**Note:**
It is not necessary to set header fields explicitly in outgoing messages as diameter itself will set appropriate values. Setting inappropriate values can be useful for test purposes.

Fields have the following types.

version = uint8()
length = uint24()
cmd_code = uint24()
application_id = uint32()
hop_by_hop_id = uint32()
end_to_end_id = uint32()

is_request = boolean()
is_proxiable = boolean()
is_error = boolean()
is_retransmitted = boolean()

Values corresponding to the R(equest), P(roxyable), Error) and T(Potentially re-transmitted message) flags of the Diameter header.

message() = record() | maybe_improper_list()
The representation of a Diameter message as passed to diameter:call/4 or returned from a handle_request/3 callback. The record representation is as outlined in diameter_dict(4): a message as defined in a dictionary file is encoded as a record with one field for each component AVP. Equivalently, a message can also be encoded as a list whose head is the atom-valued message name (as specified in the relevant dictionary file) and whose tail is either a list of AVP name/values pairs or a map with values keyed on AVP names. The format at decode is determined by diameter:service_opt() decode_format. Any of the formats is accepted at encode.
Another list-valued representation allows a message to be specified as a list whose head is a `header()` and whose tail is an `avp()` list. This representation is used by diameter itself when relaying requests as directed by the return value of a `handle_request/3` callback. It differs from the other two in that it bypasses the checks for messages that do not agree with their definitions in the dictionary in question: messages are sent exactly as specified.

```
packet() = #diameter_packet{}
```

A container for incoming and outgoing Diameter messages. Fields have the following types.

- **header** = `header()` | undefined
  - The Diameter header of the message. Can be (and typically should be) `undefined` for an outgoing message in a non-relay application, in which case diameter provides appropriate values.

- **avps** = `[avp()]` | `undefined`
  - The AVPs of the message. Ignored for an outgoing message if the `msg` field is set to a value other than `undefined`.

- **msg** = `message()` | `undefined`
  - The incoming/outgoing message. For an incoming message, a term corresponding to the configured `decode format` if the message can be decoded in a non-relay application, `undefined` otherwise. For an outgoing message, setting a `[header() | avp()]` list is equivalent to setting the `header` and `avps` fields to the corresponding values.

**Warning:**

A value in the `msg` field does **not** imply an absence of decode errors. The `errors` field should also be examined.

```
bin = binary()
```

The incoming message prior to encode or the outgoing message after encode.

```
errors = [5000..5999 | {5000..5999, avp()}]
```

Errors detected at decode of an incoming message, as identified by a corresponding 5xxx series Result-Code (Permanent Failures). For an incoming request, these should be used to formulate an appropriate answer as documented for the `handle_request/3` callback in `diameter_app(3)`. For an incoming answer, the `diameter:application_opt()` answer_errors determines the behaviour.

```
transport_data = term()
```

An arbitrary term of meaning only to the transport process in question, as documented in `diameter_transport(3)`.

### Exports

```
decode(Mod, Bin) -> Pkt
```

Types:

- **Mod** = `dictionary()`
- **Bin** = `binary()`
- **Pkt** = `packet()`

Decode a Diameter message.
encode(Mod, Msg) -> Pkt

Types:
  Mod = dictionary()
  Msg = message() | packet()
  Pkt = packet()

Encode a Diameter message.

SEE ALSO

diameter(1), diameter_app(3), diameter_dict(4), diameter_make(3)
A diameter service, as configured with `diameter:start_service/2`, specifies one or more supported Diameter applications. Each Diameter application specifies a dictionary module that knows how to encode and decode its messages and AVPs. The dictionary module is in turn generated from a file that defines these messages and AVPs. The format of such a file is defined in FILE FORMAT below. Users add support for their specific applications by creating dictionary files, compiling them to Erlang modules using either `diameterc(1)` or `diameter_make(3)` and configuring the resulting dictionaries modules on a service.

Dictionary module generation also results in a hrl file that defines records for the messages and Grouped AVPs defined by the dictionary, these records being what a user of the diameter application sends and receives, modulo other possible formats as discussed in `diameter_app(3)`. These records and the underlying Erlang data types corresponding to Diameter data formats are discussed in MESSAGE RECORDS and DATA TYPES respectively. The generated hrl also contains macro definitions for the possible values of AVPs of type Enumerated.

The diameter application includes five dictionary modules corresponding to applications defined in section 2.4 of RFC 6733: `diameter_gen_base_rfc3588` and `diameter_gen_base_rfc6733` for the Diameter Common Messages application with application identifier 0, `diameter_gen_accounting` (for RFC 3588) and `diameter_gen_acct_rfc6733` for the Diameter Base Accounting application with application identifier 3 and `diameter_gen_relay` the Relay application with application identifier 0xFFFFFFFF.

The Common Message and Relay applications are the only applications that diameter itself has any specific knowledge of. The Common Message application is used for messages that diameter itself handles: CER/CEA, DWR/DWA and DPR/DPA. The Relay application is given special treatment with regard to encode/decode since the messages and AVPs it handles are not specifically defined.

FILE FORMAT

A dictionary file consists of distinct sections. Each section starts with a tag followed by zero or more arguments and ends at the the start of the next section or end of file. Tags consist of an ampersand character followed by a keyword and are separated from their arguments by whitespace. Whitespace separates individual tokens but is otherwise insignificant.

The tags, their arguments and the contents of each corresponding section are as follows. Each section can occur multiple times unless otherwise specified. The order in which sections are specified is unimportant.

@id Number

Defines the integer Number as the Diameter Application Id of the application in question. Can occur at most once and is required if the dictionary defines @messages. The section has empty content.

The Application Id is set in the Diameter Header of outgoing messages of the application, and the value in the header of an incoming message is used to identify the relevant dictionary module.

Example:

```
@id 16777231
```

@name Mod

Defines the name of the generated dictionary module. Can occur at most once and defaults to the name of the dictionary file minus any extension. The section has empty content.

Note that a dictionary module should have a unique name so as not collide with existing modules in the system.

Example:
@prefix Diameter

@prefix Diameter.

@prefix Name

Defines Name as the prefix to be added to record and constant names (followed by a '_' character) in the generated dictionary module and hrl. Can occur at most once. The section has empty content.

A prefix is optional but can be used to disambiguate between record and constant names resulting from similarly named messages and AVPs in different Diameter applications.

Example:

@prefix etsi_e2

@vendor Number Name

Defines the integer Number as the default Vendor-Id of AVPs for which the V flag is set. Name documents the owner of the application but is otherwise unused. Can occur at most once and is required if an AVP sets the V flag and is not otherwise assigned a Vendor-Id. The section has empty content.

Example:

@vendor 13019 ETSI

@avp_vendor_id Number

Defines the integer Number as the Vendor-Id of the AVPs listed in the section content, overriding the @vendor default. The section content consists of AVP names.

Example:

@avp_vendor_id 2937

WWW-Auth
Domain-Index
Region-Set

@inherits Mod

Defines the name of a dictionary module containing AVP definitions that should be imported into the current dictionary. The section content consists of the names of those AVPs whose definitions should be imported from the dictionary, an empty list causing all to be imported. Any listed AVPs must not be defined in the current dictionary and it is an error to inherit the same AVP from more than one dictionary.

Note that an inherited AVP that sets the V flag takes its Vendor-Id from either @avp_vendor_id in the inheriting dictionary or @vendor in the inherited dictionary. In particular, @avp_vendor_id in the inherited dictionary is ignored. Inheriting from a dictionary that specifies the required @vendor is equivalent to using @avp_vendor_id with a copy of the dictionary's definitions but the former makes for easier reuse.

All dictionaries should typically inherit RFC 6733 AVPs from diameter_gen_base_rfc6733.

Example:

@inherits diameter_gen_base_rfc6733

@avp_types

Defines the name, code, type and flags of individual AVPs. The section consists of definitions of the form
Name      Code      Type      Flags
where Code is the integer AVP code. Type identifies an AVP Data Format as defined in section DATA TYPES
below, and Flags is a string of V, M and P characters indicating the flags to be set on an outgoing AVP or a single
'-' (minus) character if none are to be set.
Example:

<table>
<thead>
<tr>
<th>AVP Name</th>
<th>Code</th>
<th>Type</th>
<th>Flags</th>
</tr>
</thead>
<tbody>
<tr>
<td>Location-Information</td>
<td>350</td>
<td>Grouped</td>
<td>MV</td>
</tr>
<tr>
<td>Requested-Information</td>
<td>353</td>
<td>Enumerated</td>
<td>V</td>
</tr>
</tbody>
</table>

Warning:
The P flag has been deprecated by RFC 6733.

@custom_types Mod

Specifies AVPs for which module Mod provides encode/decode functions. The section contents consists of AVP
names. For each such name, Mod:Name(encode|decode, Type, Data, Opts) is expected to provide
encode/decode for values of the AVP, where Name is the name of the AVP, Type is it's type as declared in the
@avp_types section of the dictionary, Data is the value to encode/decode, and Opts is a term that is passed
through encode/decode.
Example:

@custom_types rfc4005_avps
  Framed-IP-Address

@codecs Mod

Like @custom_types but requires the specified module to export Mod:Type(encode|decode, Name, Data, Opts) rather than Mod:Name(encode|decode, Type, Data, Opts).
Example:

@codecs rfc4005_avps
  Framed-IP-Address

@messages

Defines the messages of the application. The section content consists of definitions of the form specified in section
3.2 of RFC 6733, "Command Code Format Specification".
@messages

RTR ::= < Diameter Header: 287, REQ, PXY >
   < Session-Id >
   { Auth-Application-Id } 
   { Auth-Session-State } 
   { Origin-Host } 
   { Origin-Realm }
   { Destination-Host }
   { SIP-Deregistration-Reason }
   [ Destination-Realm ]
   [ User-Name ]
   * [ SIP-AOR ]
   * [ Proxy-Info ]
   * [ Route-Record ]
   * [ AVP ]

RTA ::= < Diameter Header: 287, PXY >
   < Session-Id >
   { Auth-Application-Id } 
   { Result-Code } 
   { Auth-Session-State } 
   { Origin-Host } 
   { Origin-Realm }
   [ Authorization-Lifetime ]
   [ Auth-Grace-Period ]
   [ Redirect-Host ]
   [ Redirect-Host-Usage ]
   [ Redirect-Max-Cache-Time ]
   * [ Proxy-Info ]
   * [ Route-Record ]
   * [ AVP ]

@g grouped

Defines the contents of the AVPs of the application having type Grouped. The section content consists of definitions of the form specified in section 4.4 of RFC 6733, “Grouped AVP Values”.

Example:

@g grouped

SIP-Deregistration-Reason ::= < AVP Header: 383 >
   { SIP-Reason-Code }
   [ SIP-Reason-Info ]
   * [ AVP ]

Specifying a Vendor-Id in the definition of a grouped AVP is equivalent to specifying it with @avp_vendor_id.

@enum Name

Defines values of AVP Name having type Enumerated. Section content consists of names and corresponding integer values. Integer values can be prefixed with 0x to be interpreted as hexadecimal.

Note that the AVP in question can be defined in an inherited dictionary in order to introduce additional values to an enumeration otherwise defined in another dictionary.

Example:
@enum SIP-Reason-Code
  PERMANENT_TERMINATION 0
  NEW SIP_SERVER_ASSIGNED 1
  SIP_SERVER_CHANGE 2
  REMOVE_SIP_SERVER 3
@end

Causes parsing of the dictionary to terminate: any remaining content is ignored.

Comments can be included in a dictionary file using semicolon: characters from a semicolon to end of line are ignored.

**MESSAGE RECORDS**

The hrl generated from a dictionary specification defines records for the messages and grouped AVPs defined in @messages and @grouped sections. For each message or grouped AVP definition, a record is defined whose name is the message or AVP name, prefixed with any dictionary prefix defined with @prefix, and whose fields are the names of the AVPs contained in the message or grouped AVP in the order specified in the definition in question. For example, the grouped AVP

\[
\text{SIP-Deregistration-Reason ::= } < \text{ AVP Header: 383 } > \\
\hspace{1cm} \{ \text{ SIP-Reason-Code } \} \\
\hspace{1cm} [ \text{ SIP-Reason-Info } ] \\
\hspace{1cm} * \{ \text{ AVP } \}
\]

will result in the following record definition given an empty prefix.

```
-record('SIP-Deregistration-Reason', {'SIP-Reason-Code', 'SIP-Reason-Info', 'AVP'}).
```

The values encoded in the fields of generated records depends on the type and number of times the AVP can occur. In particular, an AVP which is specified as occurring exactly once is encoded as a value of the AVP’s type while an AVP with any other specification is encoded as a list of values of the AVP’s type. The AVP’s type is as specified in the AVP definition, the RFC 6733 types being described below.

**DATA TYPES**

The data formats defined in sections 4.2 ("Basic AVP Data Formats") and 4.3 ("Derived AVP Data Formats") of RFC 6733 are encoded as values of the types defined here. Values are passed to `diameter:call/4` in a request record when sending a request, returned in a resulting answer record and passed to a `handle_request/3` callback upon reception of an incoming request.

In cases in which there is a choice between string() and binary() types for OctetString() and derived types, the representation is determined by the value of `diameter:service_opt() string_decode`.

**Basic AVP Data Formats**

```
OctetString() = string() \| binary()
Integer32() = -2147483647..2147483647
Integer64() = -9223372036854775807..9223372036854775807
Unsigned32() = 0..4294967295
Unsigned64() = 0..18446744073709551615
Float32() = '-infinity' \| float() \| infinity
Float64() = '-infinity' \| float() \| infinity
Grouped() = record()
```
On encode, an `OctetString()` can be specified as an iolist(), excessively large floats (in absolute value) are equivalent to `infinity` or `'-infinity'` and excessively large integers result in encode failure. The records for grouped AVPs are as discussed in the previous section.

**Derived AVP Data Formats**

```
Address() = OctetString() |
            tuple()
```

On encode, an `OctetString()` IPv4 address is parsed in the usual x.x.x.x format while an IPv6 address is parsed in any of the formats specified by section 2.2 of RFC 2373, "Text Representation of Addresses". An IPv4 tuple() has length 4 and contains values of type 0..255. An IPv6 tuple() has length 8 and contains values of type 0..65535. The tuple representation is used on decode.

```
Time() = {date(), time()}

where

date() = {Year, Month, Day}

time() = {Hour, Minute, Second}

Year    = integer()
Month   = 1..12
Day     = 1..31
Hour    = 0..23
Minute  = 0..59
Second  = 0..59
```

Additionally, values that can be encoded are limited by way of their encoding as four octets as required by RFC 6733 with the required extension from RFC 2030. In particular, only values between `{{1968,1,20},{3,14,8}}` and `{{2104,2,26},{9,42,23}}` (both inclusive) can be encoded.

```
UTF8String() = [integer()] | binary()
```

List elements are the UTF-8 encodings of the individual characters in the string. Invalid codepoints will result in encode/decode failure. On encode, a UTF8String() can be specified as a binary, or as a nested list of binaries and codepoints.

```
DiameterIdentity() = OctetString()
```

A value must have length at least 1.

```
DiameterURI() = OctetString() |
                 #diameter_URI{type = Type,
                     fqdn = FQDN,
                     port = Port,
                     transport = Transport,
                     protocol = Protocol}

where

Type    = aaa | aaas
FQDN    = OctetString()
Port    = integer()
Transport = sctp | tcp
Protocol = diameter | radius | 'tacacs+'
```
On encode, fields port, transport and protocol default to 3868, sctp and diameter respectively. The grammar of an OctetString-valued DiameterURI() is as specified in section 4.3 of RFC 6733. The record representation is used on decode.

```plaintext
Enumerated() = Integer32()
```

On encode, values can be specified using the macros defined in a dictionary's hrl file.

```plaintext
IPFilterRule() = OctetString()
QoSFilterRule() = OctetString()
```

Values of these types are not currently parsed by diameter.

**SEE ALSO**

diameterc(1), diameter(3), diameter_app(3), diameter_codec(3), diameter_make(3)
diameter_make
Erlang module

The function `codec/2` is used to compile a diameter dictionary file into Erlang source. The resulting source implements the interface diameter requires to encode and decode the dictionary's messages and AVPs.

The utility `diameterc(1)` provides an alternate compilation interface.

Exports

`codec(File :: iolist() | binary(), [Opt]) -> ok | {ok, [Out]} | {error, Reason}`

Compile a single dictionary file. The input `File` can be either a path or a literal dictionary, the occurrence of newline (ascii NL) or carriage return (ascii CR) identifying the latter. `Opt` determines the format of the results and whether they are written to file or returned, and can have the following types.

parse | forms | erl | hrl

Specifies an output format. Whether the output is returned or written to file depends on whether or not option `return` is specified. When written to file, the resulting file(s) will have extensions `.D`, `.F`, `.erl`, and `.hrl` respectively, basenames defaulting to `dictionary` if the input dictionary is literal and does not specify `@name`. When returned, results are in the order of the corresponding format options. Format options default to `erl` and `hrl` (in this order) if unspecified.

The `parse` format is an internal representation that can be passed to `flatten/1` and `format/1`, while the `forms` format can be passed to `compile:forms/2`. The `erl` and `hrl` formats are returned as iolists.

```
{include, string()}
Prepend the specified directory to the code path. Use to point at beam files compiled from inherited dictionaries, `@inherits` in a dictionary file creating a beam dependency, not an erl/hrl dependency.

Multiple include options can be specified.
```

```
{outdir, string()}
Write generated source to the specified directory. Defaults to the current working directory. Has no effect if option `return` is specified.
```

return

Return results in a `{ok, [Out]}` tuple instead of writing to file and returning `ok`.

```
{name|prefix, string()}
Transform the input dictionary before compilation, setting `@name` or `@prefix` to the specified string.
```

```
{inherits, string()}
Transform the input dictionary before compilation, appending `@inherits` of the specified string.

Two forms have special meaning:

```
{inherits, "-"}
{inherits, "Prev/Mod"}
```

The first has the effect of clearing any previous inherits, the second of replacing a previous inherits of `Prev` to one of `Mod`. This allows the semantics of the input dictionary to be changed without modifying the file itself.
Multiple `inherits` options can be specified.

Note that a dictionary's `@name`, together with the `outdir` option, determine the output paths when the `return` option is not specified. The `@name` of a literal input dictionary defaults to `dictionary`.

A returned error reason can be converted into a readable string using `format_error/1`.

```erlang
format(Parsed) -> iolist()
```

Turns a parsed dictionary, as returned by `codec/2`, back into the dictionary format.

```erlang
flatten(Parsed) -> term()
```

Reconstitute a parsed dictionary, as returned by `codec/2`, without using `@inherits`. That is, construct an equivalent dictionary in which all AVP's are defined in the dictionary itself. The return value is also a parsed dictionary.

```erlang
format_error(Reason) -> string()
```

Turn an error reason returned by `codec/2` into a readable string.

**BUGS**

Unrecognized options are silently ignored.

**SEE ALSO**

`diameterc(1), diameter_dict(4)`
A module specified as a transport_module to diameter:add_transport/2 must implement the interface documented here. The interface consists of a function with which diameter starts a transport process and a message interface with which the transport process communicates with the process that starts it (aka its parent).

**DATA TYPES**

`message() = binary() | diameter_codec:packet()`

A Diameter message as passed over the transport interface.

For an inbound message from a transport process, a `diameter_codec:packet()` must contain the received message in its bin field. In the case of an inbound request, any value set in the transport_data field will passed back to the transport module in the corresponding answer message, unless the sender supplies another value.

For an outbound message to a transport process, a `diameter_codec:packet()` has a value other than undefined in its transport_data field and has the binary() to send in its bin field.

**Exports**

`Mod:start({Type, Ref}, Svc, Config) -> {ok, Pid} | {ok, Pid, LAddrs} | {error, Reason}`

Types:

- `Type = connect | accept`
- `Ref = diameter:transport_ref()`
- `Svc = #diameter_service()`
- `Config = term()`
- `Pid = pid()`
- `LAddrs = [inet:ip_address()]`
- `Reason = term()`

Start a transport process. Called by diameter as a consequence of a call to diameter:add_transport/2 in order to establish or accept a transport connection respectively. A transport process maintains a connection with a single remote peer.

Type indicates whether the transport process in question is being started for a connecting (Type=connect) or listening (Type=accept) transport. In the latter case, transport processes are started as required to accept connections from multiple peers.

Ref is the value that was returned from the call to diameter:add_transport/2 that has lead to starting of a transport process.

Svc contains capabilities passed to diameter:start_service/2 and diameter:add_transport/2, values passed to the latter overriding those passed to the former.

Config is as passed in transport_config tuple in the diameter:transport_opt() list passed to diameter:add_transport/2.

The start function should use the Host-IP-Address list in Svc and/or Config to select and return an appropriate list of local IP addresses. In the connecting case, the local address list can instead be communicated in a connected message (see MESSAGES below) following connection establishment. In either case, the local address list is used...
to populate Host-IP-Address AVPs in outgoing capabilities exchange messages if Host-IP-Address is unspecified.

A transport process must implement the message interface documented below. It should retain the pid of its parent, monitor the parent and terminate if it dies. It should not link to the parent. It should exit if its transport connection with its peer is lost.

MESSAGES

All messages sent over the transport interface are of the form \(\text{\{diameter, \_\}}\).

A transport process can expect messages of the following types from its parent.

\[
\text{\{diameter, \{send, message() | false\}\}}
\]

An outbound Diameter message. The atom false can only be received when request acknowledgements have been requests: see the \text{ack} message below.

\[
\text{\{diameter, \{close, Pid\}\}}
\]

A request to terminate the transport process after having received DPA in response to DPR. The transport process should exit. Pid is the pid() of the parent process.

\[
\text{\{diameter, \{tls, Ref, Type, Bool\}\}}
\]

Indication of whether or not capabilities exchange has selected inband security using TLS. Ref is a reference() that must be included in the \{diameter, \{tls, Ref\}\} reply message to the transport’s parent process (see below). Type is either connect or accept depending on whether the process has been started for a connecting or listening transport respectively. Bool is a boolean() indicating whether or not the transport connection should be upgraded to TLS.

If TLS is requested (Bool=\text{true}) then a connecting process should initiate a TLS handshake with the peer and an accepting process should prepare to accept a handshake. A successful handshake should be followed by a \{diameter, \{tls, Ref\}\} message to the parent process. A failed handshake should cause the process to exit.

This message is only sent to a transport process over whose Inband-Security-Id configuration has indicated support for TLS.

A transport process should send messages of the following types to its parent.

\[
\text{\{diameter, \{self(), connected\}\}}
\]

Inform the parent that the transport process with Type=accept has established a connection with the peer. Not sent if the transport process has Type=connect.

\[
\text{\{diameter, \{self(), connected, Remote\}\}}
\]

\[
\text{\{diameter, \{self(), connected, Remote, [LocalAddr]\}\}}
\]

Inform the parent that the transport process with Type=connect has established a connection with a peer. Not sent if the transport process has Type=accept. Remote is an arbitrary term that uniquely identifies the remote endpoint to which the transport has connected. A LocalAddr list has the same semantics as one returned from \text{start/3}.

\[
\text{\{diameter, \text{ack}\}}
\]

Request acknowledgements of unanswered requests. A transport process should send this once before passing incoming Diameter messages into diameter. As a result, every Diameter request passed into diameter with a recv message (below) will be answered with a send message (above), either a message() for the transport process to send or the atom false if the request has been discarded or otherwise not answered.

This is to allow a transport process to keep count of the number of incoming request messages that have not yet been answered or discarded, to allow it to regulate the amount of incoming traffic. Both diameter_tcp and
diameter_transport

diameter_sctp request acknowledgements when a message_cb is configured, turning send/recv message into callbacks that can be used to regulate traffic.

{diameter, {recv, message()}}

An inbound Diameter message.

{diameter, {tls, Ref}}

Acknowledgment of a successful TLS handshake. Ref is the reference() received in the {diameter, {tls, Ref, Type, Bool}} message in response to which the reply is sent. A transport must exit if a handshake is not successful.

SEE ALSO

diameter_tcp(3), diameter_sctp(3)
This module implements diameter transport over TCP using gen_tcp(3). It can be specified as the value of a transport_module option to diameter:add_transport/2 and implements the behaviour documented in diameter_transport(3). TLS security is supported, either as an upgrade following capabilities exchange or at connection establishment.

Note that the ssl application is required for TLS and must be started before configuring TLS capability on diameter transports.

### Exports

```
start({Type, Ref}, Svc, [Opt]) -> {ok, Pid} | {ok, Pid, [LAddr]} | {error, Reason}
```

**Types:**
- **Type** = connect | accept
- **Ref** = diameter:transport_ref()
- **Svc** = #diameter_service()
- **Opt** = OwnOpt | SslOpt | TcpOpt
- **Pid** = pid()
- **LAddr** = inet:ip_address()
- **Reason** = term()
- **OwnOpt** = {raddr, inet:ip_address()} | {rport, integer()} | {accept, Match} | {port, integer()} | {fragment_timer, infinity | 0..16#FFFFFFFF} | {message_cb, diameter:eval()} | {sender, boolean()}
- **SslOpt** = {ssl_options, true | list()}
- **TcpOpt** = term()
- **Match** = inet:ip_address() | string() | [Match]

The start function required by diameter_transport(3).

**Options** `raddr` and `rport` specify the remote address and port for a connecting transport and are not valid for a listening transport.

Option `accept` specifies remote addresses for a listening transport and is not valid for a connecting transport. If specified, a remote address that does not match one of the specified addresses causes the connection to be aborted. Multiple `accept` options can be specified. A string-valued `Match` that does not parse as an address is interpreted as a regular expression.

Option `ssl_options` must be specified for a transport that should support TLS: a value of `true` results in a TLS handshake immediately upon connection establishment while `list()` specifies options to be passed to `ssl:connect/2` or `ssl:ssl_accept/2` after capabilities exchange if TLS is negotiated.

Option `fragment_timer` specifies the timeout, in milliseconds, of a timer used to flush messages from the incoming byte stream even if the number of bytes indicated in the Message Length field of its Diameter Header have not yet been accumulated: such a message is received over the transport interface after two successive timeouts without the reception of additional bytes. Defaults to 1000.
Option `sender` specifies whether or not to use a dedicated process for sending outgoing messages, which avoids the possibility of send blocking reception. Defaults to `false`. If set to `true` then a `message_cb` that avoids the possibility of messages being queued in the sender process without bound should be configured.

Option `message_cb` specifies a callback that is invoked on incoming and outgoing messages, that can be used to implement flow control. It is applied to two arguments: an atom indicating the reason for the callback (send, recv, or ack after a completed send), and the message in question (binary() on recv, binary() or `diameter_packet` record on send or ack, or `false` on ack when an incoming request has been discarded). It should return a list of actions and a new callback as tail; eg. `[fun cb/3, State]`. Valid actions are the atoms `send` or `recv` to cause a following message-valued action to be sent/received, a message to send/receive (binary() or `diameter_packet` record), or a boolean() to enable/disable reading on the socket. More than one `send/recv` message sequence can be returned from the same callback, and an initial `send/recv` can be omitted if the same as the value passed as the callback's first argument. Reading is initially enabled, and returning `false` does not imply there cannot be subsequent `recv` callbacks since messages may already have been read. An empty tail is equivalent to the prevailing callback. Defaults to a callback equivalent to `fun(ack, _) -> []; (_, Msg) -> [Msg] end`.

Remaining options are any accepted by `ssl:connect/3` or `gen_tcp:connect/3` for a connecting transport, or `ssl:listen/2` or `gen_tcp:listen/2` for a listening transport, depending on whether or not `{ssl_options, true}` has been specified. Options `binary`, `packet` and `active` cannot be specified. Also, option `port` can be specified for a listening transport to specify the local listening port, the default being the standardized 3868. Note that the option `ip` specifies the local address.

An `ssl_options` list must be specified if and only if the transport in question has set `Inband-Security-Id` to 1 (TLS), as specified to either `diameter:start_service/2` or `diameter:add_transport/2`, so that the transport process will receive notification of whether or not to commence with a TLS handshake following capabilities exchange. Failing to specify an options list on a TLS-capable transport for which TLS is negotiated will cause TLS handshake to fail. Failing to specify TLS capability when `ssl_options` has been specified will cause the transport process to wait for a notification that will not be forthcoming, which will eventually cause the RFC 3539 watchdog to take down the connection.

The first element of a non-empty `Host-IP-Address` list in `Svc` provides the local IP address if an `ip` option is not specified. The local address is either returned from `start/3` or passed in a `connected` message over the transport interface.

**SEE ALSO**

`diameter(3), diameter_transport(3), gen_tcp(3), inet(3), ssl(3)`
This module implements diameter transport over SCTP using `gen_sctp(3)`. It can be specified as the value of a transport_module option to `diameter:add_transport/2` and implements the behaviour documented in `diameter_transport(3)`.

Exports

\[
\text{start} \{\text{Type}, \text{Ref}, \text{Svc}, [\text{Opt}]\} -> \{\text{ok}, \text{Pid}, \{\text{LAddr}\}\} | \{\text{error}, \text{Reason}\}
\]

Types:

- `Type = \text{connect} | \text{accept}`
- `Ref = \text{diameter:transport_ref()}`
- `Svc = \#\text{diameter_service()}`
- `Opt = \text{OwnOpt} | \text{SctpOpt}`
- `Pid = \text{pid()}`
- `LAddr = \text{inet:ip_address()}`
- `Reason = \text{term()}`
- `OwnOpt = \{\text{raddr, inet:ip_address()\} | \{\text{rport, integer()\} | \{\text{accept, Match\} | \{\text{unordered, boolean() | pos_integer()\} | \{\text{packet, boolean() | raw\} | \{\text{message_cb, diameter:eval()\} | \{\text{sender, boolean()\}
- `SctpOpt = \text{term()}`
- `Match = \text{inet:ip_address() | string()} | [\text{Match}]`

The start function required by `diameter_transport(3)`.

Options `raddr` and `rport` specify the remote address and port for a connecting transport and not valid for a listening transport: the former is required while latter defaults to 3868 if unspecified. Multiple `raddr` options can be specified, in which case the connecting transport in question attempts each in sequence until an association is established.

Option `accept` specifies remote addresses for a listening transport and is not valid for a connecting transport. If specified, a remote address that does not match one of the specified addresses causes the association to be aborted. Multiple `accept` options can be specified. A string-valued `Match` that does not parse as an address is interpreted as a regular expression.

Option `unordered` specifies whether or not to use unordered delivery, integer N being equivalent to N <= OS, where OS is the number of outbound streams negotiated on the association in question. Regardless of configuration, sending is ordered on stream 0 until reception of a second incoming message, to ensure that a peer receives capabilities exchange messages before any other. Defaults to `false`.

Option `packet` determines how/if an incoming message is packaged into a `diameter_packet` record. If `false` then messages are received as `binary()`. If `true` then as a record with the binary() message in the `bin` field and a `{stream, Id}` tuple in the `transport_data` field, where `Id` is the identifier of the inbound stream the message was received on. If `raw` then as a record with the received ancillary `sctp_sndrcvinfo` record in the `transport_data` field. Defaults to `true`.

Options `message_cb` and `sender` have semantics identical to those documented in `diameter_tcp(3)`, but with the message argument to a `recv` callback being as directed by the `packet` option.
An \{outstream, Id\} tuple in the transport_data field of a outgoing diameter_packet record sets the outbound stream on which the message is sent, modulo the negotiated number of outbound streams. Any other value causes successive such sends to cycle though all outbound streams.

Remaining options are any accepted by gen_sctp:open/1, with the exception of options mode, binary, list, active and sctp_events. Note that options ip and port specify the local address and port respectively.

Multiple ip options can be specified for a multihomed peer. If none are specified then the values of Host-IP-Address in the diameter_service record are used. Option port defaults to 3868 for a listening transport and 0 for a connecting transport.

**Warning:**

An small receive buffer may result in a peer having to resend incoming messages: set the inet(3) option recbuf to increase the buffer size.

An small send buffer may result in outgoing messages being discarded: set the inet(3) option sndbuf to increase the buffer size.

SEE ALSO

diameter(3), diameter_transport(3), gen_sctp(3), inet(3)
