STDLIB Reference Manual

Short Summaries

- Erlang Module beam_lib [page 43] – An interface to the BEAM file format
- Erlang Module c [page 47] – Command Interface Module
- Erlang Module calendar [page 52] – Local and universal time, day-of-the-week, date and time conversions
- Erlang Module dets [page 57] – A Disk Based Term Storage
- Erlang Module dict [page 70] – Key-Value Dictionary
- Erlang Module digraph [page 74] – Directed Graphs
- Erlang Module digraph_utils [page 81] – Algorithms for Directed Graphs
- Erlang Module epp [page 85] – An Erlang Code Preprocessor
- Erlang Module erl_eval [page 87] – The Erlang Meta Interpreter
- Erlang Module erl_id_trans [page 90] – An Identity Parse Transform
- Erlang Module erl_internal [page 91] – Internal Erlang Definitions
- Erlang Module erl_lint [page 93] – The Erlang Code Linter
- Erlang Module erl_parse [page 95] – The Erlang Parser
- Erlang Module erl_pp [page 98] – The Erlang Pretty Printer
- Erlang Module erl_scan [page 101] – The Erlang Token Scanner
- Erlang Module ets [page 103] – Built-In Term Storage
- Erlang Module file_sorter [page 117] – File Sorter
- Erlang Module filename [page 122] – File Name Manipulation Functions
- Erlang Module gb_sets [page 127] – General Balanced Trees
- Erlang Module gb_trees [page 130] – General Balanced Trees
- Erlang Module gen_event [page 133] – Generic Event Handling Behaviour
- Erlang Module gen_fsm [page 142] – Generic Finite State Machine Behaviour
- Erlang Module gen_server [page 151] – Generic Server Behaviour
- Erlang Module io [page 159] – Standard I/O Server Interface Functions
- Erlang Module io_lib [page 166] – IO Library Functions
- Erlang Module lib [page 169] – Interface Module
- Erlang Module lists [page 170] – List Processing Functions
- Erlang Module log_mfh [page 181] – An Event Handler which Logs Events to Disk
• Erlang Module `math` [page 182] - Mathematical Functions
• Erlang Module `orddict` [page 184] - Key-Value Dictionary as Ordered List
• Erlang Module `ordsets` [page 185] - Functions for Manipulating Sets as Ordered Lists
• Erlang Module `pg` [page 186] - Distributed, Named Process Groups
• Erlang Module `pool` [page 187] - Load Distribution Facility
• Erlang Module `proc_lib` [page 189] - Plug-in Replacements for spawn/3,4 and spawn_link/3,4.
• Erlang Module `queue` [page 193] - Abstract Data Type for FIFO Queues
• Erlang Module `random` [page 194] - Pseudo random number generation
• Erlang Module `regexp` [page 196] - Regular Expression Functions for Strings
• Erlang Module `sets` [page 201] - Functions for Set Manipulation
• Erlang Module `shell` [page 204] - The Erlang Shell
• Erlang Module `shell_default` [page 211] - Customizing the Erlang Environment
• Erlang Module `slave` [page 212] - Functions to Starting and Controlling Slave Nodes
• Erlang Module `sofs` [page 215] - Functions for Manipulating Sets of Sets
• Erlang Module `string` [page 237] - String Processing Functions
• Erlang Module `supervisor_bridge` [page 249] - Generic Supervisor Bridge Behaviour.
• Erlang Module `sys` [page 252] - A Functional Interface to System Messages
• Erlang Module `timer` [page 259] - Timer Functions
• Erlang Module `unix` [page 263] - Calls to the UNIX Shell
• Erlang Module `win32reg` [page 264] - win32reg provides access to the registry on Windows

`beam_lib`

The following functions are exported:

• `chunks(FileNameOrBinary, [ChunkRef])` - \{ok, \{Module, [ChunkData]\}\} | \{error, Module, Reason\} [page 44] Read selected chunks from a BEAM file or binary
• `version(FileNameOrBinary)` - \{ok, \{Module, Version\}\} | \{error, Module, Reason\} [page 44] Read the BEAM file's module version
• `info(FileNameOrBinary)` - \[SourceRef, \{module, Module\}, \{chunks, [ChunkInfo]\}\] | \{error, Module, Reason\} [page 44] Return some information about a BEAM file
• `cmp(FileNameOrBinary, FileNameOrBinary)` - \{ok\} | \{error, Module, Reason\} [page 44] Compare two BEAM files
• `cmp_dirs(Directory1, Directory2)` - \{Only1, Only2, Different\} | \{error, Module, Reason\} [page 45] Compare the BEAM files in two directories
• **diff_dirs(Directory1, Directory2) -> ok | {error, Module, Reason}**
  [page 45] Compares the BEAM files in two directories

• **strip(FileNameOrBinary) -> {ok, [Module, FileNameOrBinary]} | {error, Module, Reason}**
  [page 45] Removes chunks not needed by the loader from a BEAM file

• **strip_files(Files) -> {ok, [Module, FileNameOrBinary]} | {error, Module, Reason}**
  [page 45] Removes chunks not needed by the loader from BEAM files

• **strip_release(Directory) -> {ok, [Module, FileName]} | {error, Module, Reason}**
  [page 46] Removes chunks not needed by the loader from all BEAM files of a release

• **format_error(Error) -> character_list()**
  [page 46] Return an English description of a BEAM read error reply

C

The following functions are exported:

• **bt(Pid) -> void()**
  [page 47] Evaluate erlang:process_display(Pid, backtrace)

• **c(File) -> CompileResult**
  [page 47] Compile a file

• **c(File, Flags) -> CompileResult**
  [page 47] Compile a file

• **cd(Dir) -> void()**
  [page 47] Change directory

• **flush() -> void()**
  [page 48] Flush the shell message queue

• **help() -> void()**
  [page 48] Display help information

• **i() -> void()**
  [page 48] Display system information

• **i(X, Y, Z) -> void()**
  [page 48] Evaluate process_info(pid(X, Y, Z))

• **l(Module) -> void()**
  [page 48] Load code into the system

• **lc(ListOfFiles) -> Result**
  [page 48] Compile several files

• **ls() -> void()**
  [page 48] List files

• **ls(Dir) -> void()**
  [page 48] List files in Dir

• **m() -> void()**
  [page 48] List all loaded modules

• **m(Module) -> void()**
  [page 49] Display information about a module
- memory() -> TupleList
  [page 49] Return memory allocation information
- memory(MemoryType) -> int()
  [page 49] Return memory allocation information
- nc(File) -> void()
  [page 50] Compile file and loads it on multiple nodes
- nc(File, Flags) -> void()
  [page 50] Compile file and loads it on multiples nodes
- ni() -> void()
  [page 50] Display network information
- nl(Module) -> void()
  [page 50] Load module in a network
- nregs() -> void()
  [page 50] Display registered processes on all nodes
- pid(X, Y, Z) -> pid()
  [page 50] Make a Pid
- pwd() -> void()
  [page 51] Print current working directory
- q() -> void()
  [page 51] Stop the Erlang node
- regs() -> void()
  [page 51] Display registered processes
- xm(ModSpec) -> void()
  [page 51] Cross reference check a module
- zi() -> void()
  [page 51] Display system information including zombies

**calendar**

The following functions are exported:

- date_to_gregorian_days(Year, Month, Day) -> Days
  [page 52] Compute the number of days from year 0 up to the given date.
- date_to_gregorian_days(Date) -> Days
  [page 52] Compute the number of days from year 0 up to the given date.
- datetime_to_gregorian_seconds(DateTime) -> Days
  [page 52] Compute the number of seconds from year 0 up to the given date and time.
- day_of_the_week(Date) -> DayNumber
  [page 53] Compute the day of the week
- day_of_the_week(Year, Month, Day) -> DayNumber
  [page 53] Compute the day of the week
- gregorian_days_to_date(Days) -> Date
  [page 53] Compute the date given the number of gregorian days
- gregorian_seconds_to_datetime(Secs) -> DateTime
  [page 53] Compute the date given the number of gregorian days
- `is_leap_year(Year) -> bool()`  
  [page 53] Check if a year is a leap year.
- `last_day_of_the_month(Year, Month) -> int()`  
  [page 53] Compute the number of days in a month
- `local_time() -> {Date, Time}`  
  [page 54] Compute local time
- `local_time_to_universal_time({Date, Time}) -> {Date, Time}`  
  [page 54] Convert from local time to universal time.
- `now_to_local_time(Now) -> {Date, Time}`  
  [page 54] Convert now to local date and time
- `now_to_universal_time(Now) -> {Date, Time}`  
  [page 54] Convert now to date and time
- `now_to_datetime(Now) -> {Date, Time}`  
  [page 54] Convert now to date and time
- `seconds_to_daytime(Secs) -> {Days, Time}`  
  [page 54] Compute a days and time from seconds
- `seconds_to_time(Secs) -> Time`  
  [page 55] Compute time from seconds
- `time_difference(T1, T2) -> Tdiff`  
  [page 55] Compute the difference between two times
- `time_to_seconds(Time) -> Secs`  
  [page 55] Compute the number of seconds since midnight up to the given time.
- `universal_time() -> {Date, Time}`  
  [page 55] Compute universal time
- `universal_time_to_local_time({Date, Time}) -> {Date, Time}`  
  [page 55] Convert from universal time to local time.
- `valid_date(Date) -> bool()`  
  [page 56] Check if a date is valid
- `valid_date(Year, Month, Day) -> bool()`  
  [page 56] Check if a date is valid

**dets**

The following functions are exported:

- `all() -> [Name]`  
  [page 58] Return a list of the names of all open Dets tables on this node.
- `close(Name) -> ok | {error, Reason}`  
  [page 58] Close a Dets table.
- `delete(Name, Key) -> ok | {error, Reason}`  
  [page 58] Delete all objects with a given key from a Dets table.
- `delete_all_objects(Name) -> ok | {error, Reason}`  
  [page 59] Delete all objects from a Dets table.
- `delete_object(Name, Object) -> ok | {error, Reason}`  
  [page 59] Delete a given object from a Dets table.
- `first(Name) -> Key | '$end_of_table'`  
  [page 59] Return the first key stored in a Dets table.
- foldl(Function, Acc0, Name) -> Acc1 | {error, Reason}  
  [page 59] Fold a function over a Dets table.
- foldr(Function, Acc0, Name) -> Acc1 | {error, Reason}  
  [page 59] Fold a function over a Dets table.
- from_ets(Name, EtsTab) -> ok | {error, Reason}  
  [page 60] Replace the objects of a Dets table with the objects of an Ets table.
- info(Name) -> InfoList | undefined  
  [page 60] Return information about a Dets table.
- info(Name, Item) -> Value | undefined  
  [page 60] Return the information associated with a given item for a Dets table.
- init_table(Name, InitFun) -> ok | {error, Reason}  
  [page 61] Replace all objects of a Dets table.
- insert(Name, Objects) -> ok | {error, Reason}  
  [page 61] Insert one or more objects into a Dets table.
- is_dets_file(FileName) -> Bool | {error, Reason}  
  [page 61] Test for a Dets table.
- lookup(Name, Key) -> [Object] | {error, Reason}  
  [page 62] Return all objects with a given key stored in a Dets table.
- match(Continuation) -> [{[Match], Continuation2} | 'end_of_table' | {error, Reason}  
  [page 62] Match a chunk of objects stored in a Dets table and return a list of variable bindings.
- match(Name, Pattern) -> [Match] | {error, Reason}  
  [page 62] Match the objects stored in a Dets table and return a list of variable bindings.
- match(Name, Pattern, N) -> [{[Match], Continuation} | 'end_of_table' | {error, Reason}  
  [page 62] Match the first chunk of objects stored in a Dets table and return a list of variable bindings.
- match_delete{Name, Pattern} -> N | {error, Reason}  
  [page 63] Delete all objects that match a given pattern from a Dets table.
- match_object(Continuation) -> [{[Object], Continuation2} | 'end_of_table' | {error, Reason}  
  [page 63] Match a chunk of objects stored in a Dets table and return a list of objects.
- match_object{Name, Pattern} -> [Object] | {error, Reason}  
  [page 63] Match the objects stored in a Dets table and return a list of objects.
- match_object{Name, Pattern, N} -> [{[Object], Continuation} | 'end_of_table' | {error, Reason}  
  [page 64] Match the first chunk of objects stored in a Dets table and return a list of objects.
- member(Name, Key) -> Bool | {error, Reason}  
  [page 64] Test for occurrence of a key in a Dets table.
- next{Name, Key1} -> Key2 | 'end_of_table'  
  [page 64] Return the next key in a Dets table.
- open_file(Filename) -> {ok, Reference} | {error, Reason}  
  [page 65] Open an existing Dets table.
open_file(Name, Args) -> {ok, Name} | {error, Reason}
[page 65] Open a Dets table.

pid2name(Pid) -> {ok, Name} | undefined
[page 66] Return the name of the Dets table handled by a pid.

safe_fixtable(Name, Fix)
[page 66] Fix a Dets table for safe traversal.

select(Continuation) -> {Selection, Continuation2} | '$end_of_table' | {error, Reason}
[page 66] Apply a match specification to some objects stored in a Dets table.

select(Name, MatchSpec) -> Selection | {error, Reason}
[page 67] Apply a match specification to all objects stored in a Dets table.

select(Name, MatchSpec, N) -> {Selection, Continuation} | '$end_of_table' | {error, Reason}
[page 67] Apply a match specification to the first chunk of objects stored in a Dets table.

select_delete(Name, MatchSpec) -> N | {error, Reason}
[page 68] Delete all objects that match a given pattern from a Dets table.

slot(Name, I) -> '$end_of_table' | [Object] | {error, Reason}
[page 68] Return the list of objects associated with a slot of a Dets table.

sync(Name) -> ok | {error, Reason}
[page 68] Ensure that all updates made to a Dets table are written to disk.

to_ets(Name, EtsTab) -> EtsTab | {error, Reason}
[page 68] Insert all objects of a Dets table into an Ets table.

traverse(Name, Fun) -> Return | {error, Reason}
[page 68] Apply a function to all or some objects stored in a Dets table.

update_counter(Name, Key, Increment) -> Result
[page 69] Update a counter object stored in a Dets table.

dict

The following functions are exported:

append(Key, Value, Dict1) -> Dict2
[page 70] Append a value to keys in a dictionary

append_list(Key, ValList, Dict1) -> Dict2
[page 70] Append new values to keys in a dictionary

erase(Key, Dict1) -> Dict2
[page 70] Erase a key from a dictionary

fetch(Key, Dict) -> Value
[page 70] Look-up values in a dictionary

fetch_keys(Dict) -> Keys
[page 71] Return all keys in a dictionary

filter(Pred, Dict1) -> Dict2
[page 71] Choose elements which satisfy a predicate

find(Key, Dict) -> Result
[page 71] Search for a key in a dictionary
- `fold(Function, Acc0, Dict) -> Acc1`
  [page 71] Fold a function over a dictionary
- `from_list(List) -> Dict`
  [page 71] Convert a list of pairs to a dictionary
- `is_key(Key, Dict) -> bool()`  
  [page 71] Test if a key is in a dictionary.
- `map(Func, Dict1) -> Dict2`
  [page 71] Map a function over a dictionary
- `merge(Func, Dict1, Dict2) -> Dict3`
  [page 72] Merge two dictionaries
- `new() -> dictionary()`  
  [page 72] Create a dictionary
- `store(Key, Value, Dict1) -> Dict2`
  [page 72] Store a value in a dictionary
- `to_list(Dict) -> List`
  [page 72] Convert a dictionary to a list of pairs
- `update(Key, Function, Dict) -> Dict`
  [page 72] Update a value in a dictionary
- `update(Key, Function, Initial, Dict) -> Dict`
  [page 73] Update a value in a dictionary
- `update_counter(Key, Increment, Dict) -> Dict`
  [page 73] Increment a value in a dictionary

### digraph

The following functions are exported:

- `add_edge(G, E, V1, V2, Label) -> edge() | {error, Reason}`  
  [page 74] Add an edge to a digraph.
- `add_edge(G, V1, V2, Label) -> edge() | {error, Reason}`  
  [page 74] Add an edge to a digraph.
- `add_edge(G, V1, V2) -> edge() | {error, Reason}`  
  [page 74] Add an edge to a digraph.
- `add_vertex(G, V, Label) -> vertex()`  
  [page 75] Add or modify a vertex of a digraph.
- `add_vertex(G, V) -> vertex()`  
  [page 75] Add or modify a vertex of a digraph.
- `add_vertex(G) -> vertex()`  
  [page 75] Add or modify a vertex of a digraph.
- `del_edge(G, E) -> true`
  [page 75] Delete an edge from a digraph.
- `del_edges(G, Edges) -> true`
  [page 75] Delete edges from a digraph.
- `del_path(G, V1, V2) -> true`
  [page 75] Delete paths from a digraph.
- `del_vertex(G, V) -> true`
  [page 76] Delete a vertex from a digraph.
- `del_vertices(G, Vertices) -> true`
  [page 76] Delete vertices from a digraph.
- `delete(G) -> true`
  [page 76] Delete a digraph.
- `edge(G, E) -> {E, V1, V2, Label} | false`
  [page 76] Return the vertices and the label of an edge of a digraph.
- `edges(G) -> Edges`
  [page 76] Return all edges of a digraph.
- `edges(G, V) -> Edges`
  [page 76] Return the edges emanating from or incident on a vertex of a digraph.
- `get_cycle(G, V) -> Vertices | false`
  [page 77] Find one cycle in a digraph.
- `get_path(G, V1, V2) -> Vertices | false`
  [page 77] Find one path in a digraph.
- `get_short_cycle(G, V) -> Vertices | false`
  [page 77] Find one short cycle in a digraph.
- `get_short_path(G, V1, V2) -> Vertices | false`
  [page 77] Find one short path in a digraph.
- `in_degree(G, V) -> integer()`
  [page 78] Return the in-degree of a vertex of a digraph.
- `in_edges(G, V) -> Edges`
  [page 78] Return all edges incident on a vertex of a digraph.
- `in_neighbours(G, V) -> Vertices`
  [page 78] Return all in-neighbours of a vertex of a digraph.
- `info(G) -> InfoList`
  [page 78] Return information about a digraph.
- `new() -> digraph()`
  [page 79] Return a protected empty digraph, where cycles are allowed.
- `new(Type) -> digraph() | {error, Reason}`
  [page 79] Create a new empty digraph.
- `no_edges(G) -> integer() >= 0`
  [page 79] Return the number of edges of the a digraph.
- `no_vertices(G) -> integer() >= 0`
  [page 79] Return the number of vertices of a digraph.
- `out_degree(G, V) -> integer()`
  [page 79] Return the out-degree of a vertex of a digraph.
- `out_edges(G, V) -> Edges`
  [page 79] Return all edges emanating from a vertex of a digraph.
- `out_neighbours(G, V) -> Vertices`
  [page 79] Return all out-neighbours of a vertex of a digraph.
- `vertex(G, V) -> {V, Label} | false`
  [page 80] Return the label of a vertex of a digraph.
- `vertices(G) -> Vertices`
  [page 80] Return all vertices of a digraph.
digraph_utils

The following functions are exported:

- components(Digraph) -> [Component]
  [page 82] Return the components of a digraph.
- condensation(Digraph) -> CondensedDigraph
  [page 82] Return a condensed graph of a digraph.
- cyclic_strong_components(Digraph) -> [StrongComponent]
  [page 82] Return the cyclic strong components of a digraph.
- is_acyclic(Digraph) -> bool()
  [page 82] Check if a digraph is acyclic.
- loop_vertices(Digraph) -> Vertices
  [page 82] Return the vertices of a digraph included in some loop.
- postorder(Digraph) -> Vertices
  [page 83] Return the vertices of a digraph in post-order.
- preorder(Digraph) -> Vertices
  [page 83] Return the vertices of a digraph in pre-order.
- reachable(Vertices, Digraph) -> Vertices
  [page 83] Return the vertices reachable from some vertices of a digraph.
- reachable_neighbours(Vertices, Digraph) -> Vertices
  [page 83] Return the neighbours reachable from some vertices of a digraph.
- reaching(Vertices, Digraph) -> Vertices
  [page 83] Return the vertices that reach some vertices of a digraph.
- reaching_neighbours(Vertices, Digraph) -> Vertices
  [page 83] Return the neighbours that reach some vertices of a digraph.
- strong_components(Digraph) -> [StrongComponent]
  [page 84] Return the strong components of a digraph.
- subgraph(Digraph, Vertices [, Options]) -> Subgraph | {error, Reason}
  [page 84] Return a subgraph of a digraph.
- topsort(Digraph) -> Vertices | false
  [page 84] Return a topological sorting of the vertices of a digraph.

epp

The following functions are exported:

- open(FileName, IncludePath) -> {ok,Epp} | {error, ErrorDescriptor}
  [page 85] Open a file for preprocessing
- open(FileName, IncludePath, PredefMacros) -> {ok,Epp} | {error, ErrorDescriptor}
  [page 85] Open a file for preprocessing
- close(Epp) -> ok
  [page 85] Close the preprocessing of the file associated with Epp
- parse_erl_form(Epp) -> {ok, AbsForm} | {eof, Line} | {error, ErrorInfo}
  [page 85] Return the next Erlang form from the opened Erlang source file
• parse_file(FileName,IncludePath,PredefMacro) -> {ok,[Form]} |  
  {error,OpenError}  
  [page 85] Preprocess and parse an Erlang source file

erl_eval

The following functions are exported:

• exprs(Expressions, Bindings) -> {value, Value, NewBindings}  
  [page 87] Evaluate expressions
• exprs(Expressions, Bindings, LocalFunctionHandler) -> {value,  
  Value, NewBindings}  
  [page 87] Evaluate expressions
• expr(Expression, Bindings) -> { value, Value, NewBindings }  
  [page 87] Evaluate expression
• expr(Expression, Bindings, LocalFunctionHandler) -> { value, Value,  
  NewBindings }  
  [page 87] Evaluate expression
• expr_list(ExpressionList, Bindings) -> {ValueList, NewBindings}  
  [page 87] Evaluate a list of expressions
• expr_list(ExpressionList, Bindings, LocalFunctionHandler) ->  
  {ValueList, NewBindings}  
  [page 87] Evaluate a list of expressions
• new_bindings() -> BindingStruct  
  [page 88] Return a bindings structure
• bindings(BindingStruct) -> Bindings  
  [page 88] Return bindings
• binding(Name, BindingStruct) -> Binding  
  [page 88] Return bindings
• add_binding(Name, Value, Bindings) -> BindingStruct  
  [page 88] Add a binding
• del_binding(Name, Bindings) -> BindingStruct  
  [page 88] Delete a binding

erl_id_trans

The following functions are exported:

• parse_transform(Forms, Options) -> Forms  
  [page 90] Transform Erlang forms
erl_internal

The following functions are exported:

- `bif(Name, Arity) -> bool()`  
  [page 91] Test for an Erlang BIF
- `guard_bif(Name, Arity) -> bool()`  
  [page 91] Test for an Erlang BIF allowed in guards
- `type_test(Name, Arity) -> bool()`  
  [page 91] Test for a valid type test
- `arith_op(OpName, Arity) -> bool()`  
  [page 91] Test for an arithmetic operator
- `bool_op(OpName, Arity) -> bool()`  
  [page 91] Test for a Boolean operator
- `comp_op(OpName, Arity) -> bool()`  
  [page 92] Test for a comparison operator
- `list_op(OpName, Arity) -> bool()`  
  [page 92] Test for a list operator
- `send_op(OpName, Arity) -> bool()`  
  [page 92] Test for a send operator
- `op_type(OpName, Arity) -> Type`  
  [page 92] Return operator type

erl_lint

The following functions are exported:

- `module(AbsForms) -> {ok, Warnings} | {error, Errors, Warnings}`  
  [page 93] Check a module for errors
- `module(AbsForms, FileName) -> {ok, Warnings} | {error, Errors, Warnings}`  
  [page 93] Check a module for errors
- `module(AbsForms, FileName, CompileOptions) -> {ok, Warnings} | {error, Errors, Warnings}`  
  [page 93] Check a module for errors
- `is_guard_test(Expr) -> bool()`  
  [page 94] Test for a guard test
- `format_error(Errordesc) -> string()`  
  [page 94] Format an error descriptor

erl_parse

The following functions are exported:

- `parse_form(Tokens) -> {ok, AbsForm} | {error, ErrorInfo}`  
  [page 95] Parse an Erlang form
- `parse_exprs(Tokens) -> {ok, Expr, list} | {error, ErrorInfo}`  
  [page 95] Parse Erlang expressions
parse_term(Tokens) \rightarrow \{ok, Term\} | \{error, ErrorInfo\}  
    [page 95] Parse an Erlang term
format_error(ErrorDescriptor) \rightarrow \text{string}()  
    [page 96] Format an error descriptor
tokens(AbsTerm) \rightarrow \text{Tokens}  
    [page 96] Generate a list of tokens for an expression
tokens(AbsTerm, MoreTokens) \rightarrow \text{Tokens}  
    [page 96] Generate a list of tokens for an expression
normalise(AbsTerm) \rightarrow \text{Data}  
    [page 96] Convert abstract form to an Erlang term
abstract(Data) \rightarrow AbsTerm  
    [page 96] Convert a Erlang term into an abstract form

erl_pp

The following functions are exported:

form(Form) \rightarrow \text{DeepCharList}  
    [page 98] Pretty print a form
form(Form, HookFunction) \rightarrow \text{DeepCharList}  
    [page 98] Pretty print a form
attribute(Attribute) \rightarrow \text{DeepCharList}  
    [page 98] Pretty print an attribute
attribute(Attribute, HookFunction) \rightarrow \text{DeepCharList}  
    [page 98] Pretty print an attribute
function(Function) \rightarrow \text{DeepCharList}  
    [page 98] Pretty print a function
function(Function, HookFunction) \rightarrow \text{DeepCharList}  
    [page 98] Pretty print a function
guard(Guard) \rightarrow \text{DeepCharList}  
    [page 98] Pretty print a guard
guard(Guard, HookFunction) \rightarrow \text{DeepCharList}  
    [page 98] Pretty print a guard
ehrs(Expressions) \rightarrow \text{DeepCharList}  
    [page 99] Pretty print Expressions
ehrs(Expressions, HookFunction) \rightarrow \text{DeepCharList}  
    [page 99] Pretty print Expressions
ehrs(Expressions, Indent, HookFunction) \rightarrow \text{DeepCharList}  
    [page 99] Pretty print Expressions
epr(Expression) \rightarrow \text{DeepCharList}  
    [page 99] Pretty print one Expression
epr(Expression, HookFunction) \rightarrow \text{DeepCharList}  
    [page 99] Pretty print one Expression
epr(Expression, Indent, HookFunction) \rightarrow \text{DeepCharList}  
    [page 99] Pretty print one Expression
epr(Expression, Indent, Precedence, HookFunction) \rightarrow \text{DeepCharList}  
    [page 99] Pretty print one Expression
erl_scan

The following functions are exported:

- `string(CharList,StartLine) -> {ok, Tokens, EndLine} | Error`  
  [page 101] Scan a string and returns the Erlang tokens
- `string(CharList) -> {ok, Tokens, EndLine} | Error`  
  [page 101] Scan a string and returns the Erlang tokens
- `tokens(Continuation, CharList, StartLine) -> Return`  
  [page 101] Re-entrant scanner
- `reserved_word(Atom) -> bool()`  
  [page 102] Test for a reserved word
- `format_error(Descriptor) -> string()`  
  [page 102] Format an error descriptor

ets

The following functions are exported:

- `all() -> [Tab]`  
  [page 104] Return a list of all ETS tables.
- `delete(Tab) -> true`  
  [page 104] Delete an entire ETS table.
- `delete(Tab, Key) -> true`  
  [page 104] Delete all objects with a given key from an ETS table.
- `delete_all_objects(Tab) -> true`  
  [page 104] Delete all objects in an ETS table.
- `delete_object(Tab, Object) -> true`  
  [page 104] Deletes a specific from an ETS table.
- `file2tab(Filename) -> {ok, Tab} | {error, Reason}`  
  [page 104] Read an ETS table from a file.
- `first(Tab) -> Key | '$\text{end\_of\_table}'`  
  [page 104] Return the first key in an ETS table.
- `fixtable(Tab, true|false) -> true | false`  
  [page 105] Fix an ETS table for safe traversal (obsolete).
- `foldl(Function, Acc0, Tab) -> Acc1`  
  [page 105] Fold a function over an ETS table
- `foldr(Function, Acc0, Tab) -> Acc1`  
  [page 105] Fold a function over an ETS table
- `from_dets(Tab, DetsTab) -> Tab`  
  [page 105] Fill an ETS table with the objects from a DETS table.
- `i() -> void()`  
  [page 106] Display information about all ETS tables on tty.
- `i(Tab) -> void()`  
  [page 106] Browse an ETS table on tty.
- `info(Tab) -> [{Item,Value}] | undefined`  
  [page 106] Return information about an ETS table.
- `info(Tab, Item) -> Value | undefined`
  [page 106] Return the information associated with given item for an ETS table.
- `init_table(Name, InitFun) -> true`
  [page 107] Replace all objects of an ETS table.
- `insert(Tab, ObjectOrObjects) -> true`
  [page 107] Insert an object into an ETS table.
- `last(Tab) -> Key | '$end_of_table'
  [page 107] Return the last key in an ETS table of type ordered_set.
- `lookup(Tab, Key) -> [Object]`
  [page 108] Return all objects with a given key in an ETS table.
- `lookup_element(Tab, Key, Pos) -> Elem`
  [page 108] Return the Pos:th element of all objects with a given key in an ETS table.
- `match(Tab, Pattern) -> [Match]`
  [page 108] Match the objects in an ETS table against a pattern.
- `match(Tab, Pattern, Limit) -> [{[Match],Continuation} | '$end_of_table']`
  [page 109] Match the objects in an ETS table against a pattern and returns part of the answers.
- `match(Continuation) -> [{[Match],Continuation} | '$end_of_table']`
- `match_delete(Tab, Pattern) -> true`
  [page 109] Delete all objects which match a given pattern from an ETS table.
- `match_object(Tab, Pattern) -> [Object]`
  [page 109] Match the objects in an ETS table against a pattern.
- `match_object(Tab, Pattern, Limit) -> [{[Match],Continuation} | '$end_of_table']`
  [page 110] Match the objects in an ETS table against a pattern and returns part of the answers.
- `match_object(Continuation) -> [{[Match],Continuation} | '$end_of_table']`
  [page 110] Continues matching objects in an ETS table.
- `member(Tab, Key) -> true | false`
- `new(Name, Options) -> tid()`
  [page 110] Create a new ETS table.
- `next(Tab, Key1) -> Key2 | '$end_of_table'
  [page 111] Return the next key in an ETS table.
- `prev(Tab, Key1) -> Key2 | '$end_of_table'
  [page 112] Return the previous key in an ETS table of type ordered_set.
- `rename(Tab, Name) -> Name`
  [page 112] Rename a named ETS table.
- `safe_fixtable(Tab, true|false) -> true | false`
  [page 112] Fix an ETS table for safe traversal.
- `select(Tab, MatchSpec) -> [Object]`
  [page 113] Match the objects in an ETS table against a match_spec.
- `select(Tab, MatchSpec, Limit) -> [Match],Continuation | '$end_of_table'`
  [page 114] Match the objects in an ETS table against a match spec and returns part of the answers
- `select(Continuation) -> [Match],Continuation | '$end_of_table'`
  [page 114] Continues matching objects in an ETS table.
- `slot(Tab, I) -> [Object] | '$end_of_table'`
  [page 115] Return all objects in a given slot of an ETS table.
- `tab2file(Tab, Filename) -> ok | {error,Reason}`
  [page 115] Dump an ETS table to a file.
- `tab2list(Tab) -> [Object]`
  [page 115] Return a list of all objects in an ETS table.
- `test_ms(Tuple, MatchSpec) -> ok, Result | {error,Errors}`
- `to_dets(Tab, DetsTab) -> Tab`
  [page 116] Fill a DETS table withe objects from an ETS table.
- `update_counter(Tab, Key, {Pos,Incr}) -> Result`
  [page 116] Update a counter object in an ETS table.
- `update_counter(Tab, Key, Incr) -> Result`
  [page 116] Update a counter object in an ETS table.

**file_sorter**

The following functions are exported:

- `sort(FileName) -> Reply`
  [page 120] Sort terms on files
- `sort(Input, Output) -> Reply`
  [page 120] Sort terms on files
- `sort(Input, Output, Options) -> Reply`
  [page 120] Sort terms on files
- `keysort(KeyPos, FileName) -> Reply`
  [page 120] Sort terms on files by key
- `keysort(KeyPos, Input, Output) -> Reply`
  [page 120] Sort terms on files by key
- `keysort(KeyPos, Input, Output, Options) -> Reply`
  [page 120] Sort terms on files by key
- `merge(FileNames, Output) -> Reply`
  [page 120] Merge terms on files
- `merge(FileNames, Output, Options) -> Reply`
  [page 120] Merge terms on files
- `keymerge(KeyPos, FileNames, Output) -> Reply`
  [page 120] Merge terms on files by key
- `keymerge(KeyPos, FileNames, Output, Options) -> Reply`
  [page 120] Merge terms on files by key
- `check(FileName) -> Reply`
  [page 121] Check whether terms on files are sorted
check(Filenames, Options) -> Reply
[page 121] Check whether terms on files are sorted

keycheck(KeyPos, FileName) -> CheckReply
[page 121] Check whether terms on files are sorted by key

keycheck(KeyPos, Filenames, Options) -> Reply
[page 121] Check whether terms on files are sorted by key

**filename**

The following functions are exported:

- **absname(Filename)** -> **Absname**
  [page 122] Convert a relative Filename to an absolute name

- **absname(Filename, Directory)** -> **Absname**
  [page 122] Convert the relative Filename to an absolute name, based on Directory.

- **basename(Filename)**
  [page 123] Return the part of the Filename after the last directory separator

- **basename(Filename, Ext)** -> **string()**
  [page 123] Return the last component of Filename with Ext stripped

- **dirname(Filename)** -> **string()**
  [page 123] Return the directory part of a path name

- **extension(Filename)** -> **string() | []**
  [page 123] Return the file extension

- **join(Components)** -> **string()**
  [page 124] Join a list of file name Components with directory separators

- **join(Name1, Name2)** -> **string()**
  [page 124] Join two file name components with directory separators.

- **nativename(Path)** -> **string()**
  [page 124] Return the native form of a file Path

- **pathtype(Path)** -> **absolute | relative | volumerelative**
  [page 124] Return the type of a Path

- **rootname(Filename)** -> **string()**
  [page 125] Return all characters in Filename, except the extension.

- **rootname(Filename, Ext)** -> **string()**
  [page 125] Return all characters in Filename, except the extension.

- **split(Filename)** -> **Components**
  [page 125] Return a list whose elements are the file name components of Filename.

- **find_src(Module)** -> **{SourceFile, Options}**
  [page 125] Find the Filename and compilation options for a compiled Module.

- **find_src(Module, Rules)** -> **{SourceFile, Options}**
  [page 125] Find the Filename and compilation options for a compiled Module.
gb_sets

The following functions are exported:

- empty()  
  [page 127] get empty set
- is_empty(S)  
  [page 127] check if empty
- size(S)  
  [page 127] get number of elements
- singleton(X)  
  [page 127] new set with one element
- is_member(X, S)  
  [page 127] check for member
- insert(X, S)  
  [page 128] insert new element
- add(X, S)  
  [page 128] add element
- delete(X, S)  
  [page 128] delete element
- balance(S)  
  [page 128] rebalance tree representation
- union(S1, S2)  
  [page 128] union of set
- union(Ss)  
  [page 128] union of list of sets
- intersection(S1, S2)  
  [page 128] intersection of sets
- intersection(Ss)  
  [page 128] intersection of list of sets
- difference(S1, S2)  
  [page 128] difference of sets
- is_subset(S1, S2)  
  [page 128] check for subset
- to_list(S)  
  [page 129] get list from set
- from_list(List)  
  [page 129] make set from list
- from_ordset(L)  
  [page 129] make set from ordset
- take_smallest(S)  
  [page 129] extract smallest element
- iterator(S)  
  [page 129] make iterator on set
- next(T)  
  [page 129] traverse with iterator
- `filter(P, S)`
  - [page 129] filter with predicate
- `fold(F, A, S)`
  - [page 129] fold with fun
- `is_set(S)`
  - [page 129] not recommended

**gb_trees**

The following functions are exported:

- `empty()`
  - [page 130] returns empty tree
- `is_empty(T)`
  - [page 130] true if tree is empty
- `size(T)`
  - [page 130] number of nodes in tree
- `lookup(X, T)`
  - [page 130] looks up key in tree
- `get(X, T)`
  - [page 130] retrieves value stored with key
- `insert(X, V, T)`
  - [page 131] inserts key and value in tree
- `update(X, V, T)`
  - [page 131] updates key to new value
- `enter(X, V, T)`
  - [page 131] inserts or updates key with value
- `delete(X, T)`
  - [page 131] removes key
- `delete_any(X, T)`
  - [page 131] removes key if present
- `balance(T)`
  - [page 131] rebalance tree
- `is_defined(X, T)`
  - [page 131] check if key exist
- `keys(T)`
  - [page 131] keys as list
- `values(T)`
  - [page 131] values as list
- `to_list(T)`
  - [page 131] keys and values as tuple-list
- `from_orrdict(L)`
  - [page 131] make tree from orddict
- `take_smallest(T)`
  - [page 132] extract smallest key
- `iterator(T)`
  - [page 132] get iterator on tree
- `next(S)`
  - [page 132] iterate using iterator
gen_event

The following functions are exported:

- `start() -> Result`
  - [page 134] Create a generic event manager.
- `start(EventMgrName) -> Result`
  - [page 134] Create a generic event manager.
- `start_link() -> Result`
  - [page 134] Create a generic event manager.
- `start_link(EventMgrName) -> Result`
  - [page 134] Create a generic event manager.
- `add_handler(EventMgrRef, Handler, Args) -> Result`
  - [page 134] Add an event handler to a generic event manager.
- `add_sup_handler(EventMgrRef, Handler, Args) -> Result`
  - [page 135] Add a supervised event handler to a generic event manager.
- `notify(EventMgrRef, Event) -> ok`
  - [page 135] Notify an event manager about an event.
- `sync_notify(EventMgrRef, Event) -> ok`
  - [page 135] Notify an event manager about an event.
- `call(EventMgrRef, Handler, Request) -> Result`
  - [page 136] Make a synchronous call to a generic event manager.
- `call(EventMgrRef, Handler, Request, Timeout) -> Result`
  - [page 136] Make a synchronous call to a generic event manager.
- `delete_handler(EventMgrRef, Handler, Args) -> Result`
  - [page 136] Delete an event handler from a generic event manager.
- `swap_handler(EventMgrRef, Handler1, Args1, Handler2, Args2) -> Result`
  - [page 137] Replace an event handler in a generic event manager.
- `swap_sup_handler(EventMgrRef, Handler1, Args1, Handler2, Args2) -> Result`
  - [page 138] Replace an event handler in a generic event manager.
- `which_handlers(EventMgrRef) -> [Handler]`
  - [page 138] Return all event handlers installed in a generic event manager.
- `stop(EventMgrRef) -> ok`
  - [page 138] Terminate a generic event manager.
- `Module:init(InitArgs) -> {ok, State}`
  - [page 139] Initialize an event handler.
- `Module:handle_event(Event, State) -> Result`
  - [page 139] Handle an event.
- `Module:handle_call(Request, State) -> Result`
  - [page 140] Handle a synchronous request.
- `Module:handle_info(Info, State) -> Result`
  - [page 140] Handle an incoming message.
- `Module:terminate(Arg, State) -> term()`
  - [page 140] Clean up before deletion.
- `Module:code_change(OldVsn, State, Extra) -> {ok, NewState}`
  - [page 141] Update the internal state due to code replacement.
gen_fsm

The following functions are exported:

- \texttt{start(Module, Args, Options) -> Result}
  [page 143] Create a generic FSM process.
- \texttt{start(FsmName, Module, Args, Options) -> Result}
  [page 143] Create a generic FSM process.
- \texttt{start_link(Module, Args, Options) -> Result}
  [page 143] Create a generic FSM process.
- \texttt{start_link(FsmName, Module, Args, Options) -> Result}
  [page 143] Create a generic FSM process.
- \texttt{send_event(FsmRef, Event) -> ok}
  [page 143] Send an event asynchronously to a generic FSM.
- \texttt{send_all_state_event(FsmRef, Event) -> ok}
  [page 144] Send an event asynchronously to a generic FSM.
- \texttt{sync_send_event(FsmRef, Event) -> Reply}
  [page 144] Send an event synchronously to a generic FSM.
- \texttt{sync_send_event(FsmRef, Event, Timeout) -> Reply}
  [page 144] Send an event synchronously to a generic FSM.
- \texttt{sync_send_all_state_event(FsmRef, Event) -> Reply}
  [page 145] Send an event synchronously to a generic FSM.
- \texttt{sync_send_all_state_event(FsmRef, Event, Timeout) -> Reply}
  [page 145] Send an event synchronously to a generic FSM.
- \texttt{reply(Caller, Reply) -> true}
  [page 145] Send a reply to a caller.
- \texttt{Module:init(Args) -> Result}
  [page 146] Initialize process and internal state name and state data.
- \texttt{Module:StateName(Event, StateData) -> Result}
  [page 146] Handle an asynchronous event.
- \texttt{Module:handle_event(Event, StateName, StateData) -> Result}
  [page 147] Handle an asynchronous event.
- \texttt{Module:StateName(Event, From, StateData) -> Result}
  [page 147] Handle a synchronous event.
- \texttt{Module:handle_sync_event(Event, From, StateName, StateData) -> Result}
  [page 148] Handle a synchronous event.
- \texttt{Module:handle_info(Info, StateName, StateData) -> Result}
- \texttt{Module:terminate(Reason, StateName, StateData)}
  [page 149] Clean up before termination.
- \texttt{Module:code_change(OldVsn, StateName, StateData, Extra) -> \{ok, NextStateName, NewStateData\}}
  [page 149] Update the state data due to code replacement.
gen_server

The following functions are exported:

- `start(Module, Args, Options) -> Result`  
  [page 151] Create a generic server process.
- `start(ServerName, Module, Args, Options) -> Result`  
  [page 151] Create a generic server process.
- `start_link(Module, Args, Options) -> Result`  
  [page 151] Create a generic server process.
- `start_link(ServerName, Module, Args, Options) -> Result`  
  [page 151] Create a generic server process.
- `call(ServerRef, Request) -> Reply`  
  [page 152] Make a synchronous call to a generic server.
- `call(ServerRef, Request, Timeout) -> Reply`  
  [page 152] Make a synchronous call to a generic server.
- `multi_call(Name, Request) -> Result`  
  [page 153] Make a synchronous call to several generic servers.
- `multi_call(Nodes, Name, Request) -> Result`  
  [page 153] Make a synchronous call to several generic servers.
- `multi_call(Nodes, Name, Request, Timeout) -> Result`  
  [page 153] Make a synchronous call to several generic servers.
- `cast(ServerRef, Request) -> ok`  
  [page 154] Send an asynchronous request to a generic server.
- `abcast(Name, Request) -> abcast`  
  [page 154] Send an asynchronous request to several generic servers.
- `abcast(Nodes, Name, Request) -> abcast`  
  [page 154] Send an asynchronous request to several generic servers.
- `reply(Client, Reply) -> true`  
  [page 155] Send a reply to a client.
- `Module:init(Args) -> Result`  
  [page 155] Initialize process and internal state.
- `Module:handle_call(Request, From, State) -> Result`  
  [page 155] Handle a synchronous request.
- `Module:handle_cast(Request, State) -> Result`  
  [page 156] Handle an asynchronous request.
- `Module:handle_info(Info, State) -> Result`  
  [page 156] Handle an incoming message.
- `Module:terminate(Reason, State)`  
  [page 157] Clean up before termination.
- `Module:code_change(OldVsn, State, Extra) -> {ok, NewState}`  
  [page 157] Update the internal state due to code replacement.
io

The following functions are exported:

- `put_chars([IoDevice,] Chars)`  
  [page 159] Write characters to standard output
- `nl([IoDevice])`  
  [page 159] Output a newline
- `get_chars([IoDevice,] Prompt, Count)`  
  [page 159] Read characters from standard input
- `get_line([IoDevice,] Prompt)`  
  [page 159] Read a line from standard input
- `write([IoDevice,] Term)`  
  [page 159] Write a term
- `read([IoDevice,] Prompt)`  
  [page 159] Read a term
- `fwrite(Format)`  
  [page 160] Write formatted output
- `format(Format)`  
  [page 160] Write formatted output
- `fwrite([IoDevice,] Format, Arguments)`  
  [page 160] Write formatted output
- `format([IoDevice,] Format, Arguments)`  
  [page 160] Write formatted output
- `fread([IoDevice,] Prompt, Format)`  
  [page 163] Read formatted input
- `scannerl_exprs(Prompt)`  
  [page 164] Read Erlang tokens
- `scannerl_exprs([IoDevice,] Prompt, StartLine)`  
  [page 164] Read Erlang tokens
- `scannerl_form(Prompt)`  
  [page 164] Read Erlang tokens
- `scannerl_form(IoDevice, Prompt[, StartLine])`  
  [page 164] Read Erlang tokens
- `parse_erl_exprs(Prompt)`  
  [page 164] Read Erlang expressions
- `parse_erl_exprs(IoDevice, Prompt[, StartLine])`  
  [page 164] Read Erlang expressions
- `parse_erl_form(Prompt)`  
  [page 165] Read Erlang form
- `parse_erl_form(IoDevice, Prompt[, StartLine])`  
  [page 165] Read Erlang form
io_lib

The following functions are exported:

- `nl()`  
  [page 166] Return a newline
- `write(Term)`  
  [page 166] Write a term
- `write(Term, Depth)`  
  [page 166] Write a term
- `print(Term)`  
  [page 166] Pretty print a term
- `print(Term, Column, LineLength, Depth)`  
  [page 166] Pretty print a term
- `fwrite(Format, Data)`  
  [page 166] List formatted output
- `format(Format, Data)`  
  [page 166] List formatted output
- `fread(Format, String)`  
  [page 166] List formatted input
- `fread(Continuation, CharList, Format)`  
  [page 167] Re-entrant formatted reader
- `write_atom(Atom)`  
  [page 167] Return an atom
- `write_string(String)`  
  [page 167] Return a string
- `write_char(Integer)`  
  [page 167] Return a character
- `indentation(String, StartIndent)`  
  [page 167] Indentation after printing string
- `char_list(CharList) -> bool()`  
  [page 167] Test for a list of characters
- `deep_char_list(CharList)`  
  [page 168] Test for a deep list of characters
- `printable_list(CharList)`  
  [page 168] Test for a list of printable characters

lib

The following functions are exported:

- `flush_receive() -> void()`  
  [page 169] Flush messages
- `error_message(Format, Args)`  
  [page 169] Print error message
- `progname() -> atom()`  
  [page 169] Return Erlang starter
• `nonl(List1)`
  [page 169] Remove last newline

• `send(To, Msg)`
  [page 169] Send a message

• `sendw(To, Msg)`
  [page 169] Send a message and waits fo an answer

lists

The following functions are exported:

• `append(ListOfLists) -> List1`
  [page 170] Append a list of lists

• `append(List1, List2) -> List3`
  [page 170] Append two lists

• `concat(Things) -> string()`
  [page 171] Concatenate a list of atoms

• `delete(Element, List1) -> List2`
  [page 171] Delete an element in a list

• `duplicate(N, Element) -> List`
  [page 171] Make N copies of element

• `flatlength(DeepList) -> int()`
  [page 171] Length of flattened deep list

• `flatten(DeepList) -> List`
  [page 171] Flatten a deep list

• `flatten(DeepList, Tail) -> List`
  [page 171] Flatten a deep list

• `keydelete(Key, N, TupleList1) -> TupleList2`
  [page 172] Delete a tuple for a tuple list

• `keymember(Key, N, TupleList) -> bool()`
  [page 172] Test for a key in a list of tuples

• `keymerge(N, List1, List2)`
  [page 172] Merge two key-sorted lists

• `keyreplace(Key, N, TupleList1, NewTuple) -> TupleList2`
  [page 172] Replace tuple in tuple list

• `keysearch(Key, N, TupleList) -> Result`
  [page 172] Extract value of key in a list of tuples

• `keysort(N, List1) -> List2`
  [page 172] Sort a list by key

• `last(List) -> Element`
  [page 173] Return last element in a list

• `max(List) -> Max`
  [page 173] Return maximum element of list

• `member(Element, List) -> bool()`
  [page 173] Test for membership of a list

• `merge(ListOfLists) -> List1`
  [page 173] Merge a list of sorted lists
- `merge(List1, List2) -> List3`
  [page 173] Merge two sorted lists
- `merge(Fun, List1, List2) -> List`
  [page 173] Merge two sorted lists
- `merge3(List1, List2, List3) -> List4`
  [page 174] Merge three sorted lists
- `min(List) -> Min`
  [page 174] Return minimum element of list
- `nth(N, List) -> Element`
  [page 174] Extract element from a list
- `nthtail(N, List1) -> List2`
  [page 174] Return the N'th tail in List1
- `prefix(List1, List2) -> bool()`
  [page 174] Test for list prefix
- `reverse(List1) -> List2`
  [page 174] Reverse a list
- `reverse(List1, List2) -> List3`
  [page 175] Reverse a list appending a tail
- `seq(From, To) -> [int()]`
  [page 175] Generate a sequence of integers
- `seq(From, To, Incr) -> [int()]`
  [page 175] Generate a sequence of integers
- `sort(List1) -> List2`
  [page 175] Sort a list
- `sort(Fun, List1) -> List2`
  [page 175] Sort a list
- `sublist(List, N) -> List1`
  [page 175] Return the first N elements of List
- `sublist(List1, Start, Length) -> List2`
  [page 176] Return a sub-list of list
- `subtract(List1, List2) -> List3`
  [page 176] Subtract the element in one list from another list
- `suffix(List1, List2) -> bool()`
  [page 176] Test for list suffix
- `sum(List) -> number()`
  [page 176] Return sum of elements in a list
- `ukeymerge(N, List1, List2)`
  [page 176] Merge two key-sorted lists and remove consecutive duplicates
- `ukeysort(N, List1) -> List2`
  [page 176] Sort a list by key and remove consecutive duplicates
- `umerge(ListOfLists) -> List1`
  [page 177] Merge a list of sorted lists without duplicates
- `umerge(List1, List2) -> List3`
  [page 177] Merge two sorted lists without duplicates
- `umerge(Fun, List1, List2) -> List`
  [page 177] Sort a list
• `umerge3(List1, List2, List3) -> List4`
  [page 177] Merge three sorted lists without duplicates

• `usort(List1) -> List2`
  [page 177] Sort a list and remove duplicates

• `usort(Fun, List1) -> List2`
  [page 177] Sort a list and remove duplicates

• `all(Pred, List) -> bool()`
  [page 178] Return true if all elements in the list satisfy Pred

• `any(Pred, List) -> bool()`
  [page 178] Return true if any of the elements X in the list satisfies Pred(X)

• `dropwhile(Pred, List1) -> List2`
  [page 178] Drop elements from List1 while Pred is true

• `filter(Pred, List1) -> List2`
  [page 178] Choose elements which satisfy a predicate

• `flatmap(Function, List1) -> Element`
  [page 178] Map and flatten in one pass

• `foldl(Function, Acc0, List) -> Acc1`
  [page 178] Fold a function over a list

• `foldr(Function, Acc0, List) -> Acc1`
  [page 179] Fold a function over a list

• `foreach(Function, List) -> void()`
  [page 179] Apply function to each element of a list

• `map(Func, List1) -> List2`
  [page 179] Map a function over a list

• `mapfoldl(Function, Acc0, List1) -> {List2, Acc}`
  [page 179] Map and fold in one pass

• `mapfoldr(Function, Acc0, List1) -> {List2, Acc}`
  [page 180] Map and fold in one pass

• `splitwith(Pred, List) -> {List1, List2}`
  [page 180] Partition List1 into two lists according to Pred

• `takewhile(Pred, List1) -> List2`
  [page 180] Take elements from List1 while Pred is true

log_mf.h

The following functions are exported:

• `init(Dir, MaxBytes, MaxFiles)`
  [page 181] Initiate the event handler

• `init(Dir, MaxBytes, MaxFiles, Pred) -> Args`
  [page 181] Initiate the event handler
math

The following functions are exported:

- `pi()` -> `float()`  [page 182] A useful number
- `sin(X)`  [page 182] Diverse math functions
- `cos(X)`  [page 182] Diverse math functions
- `tan(X)`  [page 182] Diverse math functions
- `asin(X)`  [page 182] Diverse math functions
- `acos(X)`  [page 182] Diverse math functions
- `atan(X)`  [page 182] Diverse math functions
- `atan2(Y, X)`  [page 182] Diverse math functions
- `sinh(X)`  [page 182] Diverse math functions
- `cosh(X)`  [page 182] Diverse math functions
- `tanh(X)`  [page 182] Diverse math functions
- `asinh(X)`  [page 182] Diverse math functions
- `acosh(X)`  [page 182] Diverse math functions
- `atanh(X)`  [page 182] Diverse math functions
- `exp(X)`  [page 182] Diverse math functions
- `log(X)`  [page 182] Diverse math functions
- `log10(X)`  [page 182] Diverse math functions
- `pow(X, Y)`  [page 182] Diverse math functions
- `sqrt(X)`  [page 182] Diverse math functions
- `erf(X)` -> `float()`  [page 182] Error function.
- `erfc(X)` -> `float()`  [page 183] Another error function
orddict

No functions are exported.

ordsets

No functions are exported.

pg

The following functions are exported:

- `create(PgName)`  
  [page 186] Create an empty group
- `create(PgName, Node)`  
  [page 186] Create an empty group on a node
- `join(PgName, Pid)`  
  [page 186] Join a Pid to a process group
- `send(Pgname, Message)`  
  [page 186] Send a message tuple to all members of a process group
- `esend(PgName, Mess)`  
  [page 186] Send a message tuple to all members of a process group except the current node
- `members(PgName)`  
  [page 186] Return a list of the current members in the process group

pool

The following functions are exported:

- `start(Name)`  
  [page 187] Start a new pool
- `start(Name, Args)`  
  [page 187] Start a new pool
- `attach(Node)`  
  [page 187] Ensure that a pool master is running
- `stop()`  
  [page 187] Stop the pool and kill all the slave nodes
- `get_nodes()`  
  [page 188] Return a list of the current member nodes of the pool
- `pspawn(Mod, Fun, Args)`  
  [page 188] Spawn a process on the expected lowest future loaded pool node
- `pspawn_link(Mod, Fun, Args)`  
  [page 188] Spawn links a process on the expected lowest future loaded pool node
- `get_node()`  
  [page 188] Return the node ID of the expected lowest future loaded node
- `new_node(Host, Name)`  
  [page 188] Start a new node and attach it to an already existing pool
proc_lib

The following functions are exported:

- `spawn(Module, Func, Args) -> Pid`
  [page 189] Spawn a new process
- `spawn(Node, Module, Func, Args) -> Pid`
  [page 189] Spawn a new process
- `spawn_link(Module, Func, Args) -> Pid`
  [page 189] Spawn a new process and sets a link
- `spawn_link(Node, Module, Func, Args) -> Pid`
  [page 189] Spawn a new process and sets a link
- `start(Module, Func, Args) -> Ret`
  [page 190] Start a new process synchronously
- `start(Module, Func, Args, Time) -> Ret`
  [page 190] Start a new process synchronously
- `start_link(Module, Func, Args) -> Ret`
  [page 190] Start a new process synchronously
- `start_link(Module, Func, Args, Time) -> Ret`
  [page 190] Start a new process synchronously
- `init_ack(Parent, Ret) -> void()`
  [page 190] Used by a process when it has started
- `init_ack(Ret) -> void()`
  [page 190] Used by a process when it has started
- `format(CrashReport) -> string()`
  [page 191] Format a crash report
- `initial_call(PidOrPinfo) -> {Module, Function, Args} | false`
  [page 191] Extract the initial call of a proc_lib spawned process
- `translate_initial_call(PidOrPinfo) -> {Module, Function, Arity}`
  [page 191] Extract and translate the initial call of a proc_lib spawned process

queue

The following functions are exported:

- `new() -> Queue`
  [page 193] Create a new empty FIFO queue
- `in(Item, Q1) -> Q2`
  [page 193] Insert an item into a queue
- `out(Q) -> Result`
  [page 193] Remove an item from a queue
- `to_list(Q) -> list()`
  [page 193] Convert a queue to a list
random

The following functions are exported:

- `seed() -> ran()`  
  [page 194] Seeds random number generation with default values
- `seed(A1, A2, A3) -> ran()`  
  [page 194] Seeds random number generator
- `seed0() -> ran()`  
  [page 194] Return default state for random number generation
- `uniform() -> float()`  
  [page 194] Return a random float
- `uniform(N) -> int()`  
  [page 194] Return a random integer
- `uniform(State0) -> {float(), State1}`  
  [page 195] Return a random float
- `uniform(N, State0) -> {int(), State1}`  
  [page 195] Return a random integer

regexp

The following functions are exported:

- `match(String, RegExp) -> MatchRes`  
  [page 196] Match a regular expression
- `first_match(String, RegExp) -> MatchRes`  
  [page 196] Match a regular expression
- `matches(String, RegExp) -> MatchRes`  
  [page 196] Match a regular expression
- `sub(String, RegExp, New) -> SubRes`  
  [page 197] Substitute the first occurrence of a regular expression
- `gsub(String, RegExp, New) -> SubRes`  
  [page 197] Substitute all occurrences of a regular expression
- `split(String, RegExp) -> SplitRes`  
  [page 197] Split a string into fields
- `sh_to_awk(ShRegExp) -> AwkRegExp`  
  [page 198] Convert an sh regular expression into an AWK one
- `parse(RegExp) -> ParseRes`  
  [page 198] Parse a regular expression
- `format_error(ErrorDescriptor) -> string()`  
  [page 198] Format an error descriptor
sets

The following functions are exported:

- `new()` -> `Set`
  [page 201] Return an empty set
- `is_set(Set)` -> `bool()`
  [page 201] Test for an `Set`
- `size(Set)` -> `int()`
  [page 201] Return the number of elements in a set
- `to_list(Set)` -> `List`
  [page 201] Convert an `Set` into a list
- `from_list(List)` -> `Set`
  [page 201] Convert a list into an `Set`
- `is_element(Element, Set)` -> `bool()`
  [page 201] Test for membership of an `Set`
- `add_element(Element, Set1)` -> `Set2`
  [page 202] Add an element to an `Set`
- `del_element(Element, Set1)` -> `Set2`
  [page 202] Remove an element from an `Set`
- `union(Set1, Set2)` -> `Set3`
  [page 202] Return the union of two `Sets`
- `union(SetList)` -> `Set`
  [page 202] Return the union of a list of `Sets`
- `intersection(Set1, Set2)` -> `Set3`
  [page 202] Return the intersection of two `Sets`
- `intersection(SetList)` -> `Set`
  [page 202] Return the intersection of a list of `Sets`
- `subtract(Set1, Set2)` -> `Set3`
  [page 202] Return the difference of two `Sets`
- `is_subset(Set1, Set2)` -> `bool()`
  [page 203] Test for subset
- `fold(Function, Acc0, Set)` -> `Acc1`
  [page 203] Fold over set elements
- `filter(Pred, Set1)` -> `Set2`
  [page 203] Filter set elements

shell

The following functions are exported:

- `history(N)` -> `integer()`
  [page 210] Sets the number of previous commands to keep
- `results(N)` -> `integer()`
  [page 210] Sets the number of previous commands to keep
shell_default

No functions are exported.

slave

The following functions are exported:

- `start(Host)`
  [page 212] Start a slave node at Host
- `start_link(Host)`
  [page 212] Start a slave node at Host
- `start(Host, Name)`
  [page 212] Start a slave node at Host called Name@Host
- `start_link(Host, Name)`
  [page 213] Start a slave node at Host called Name@Host
- `start(Host, Name, Args) -> {ok, Node} | {error, ErrorInfo}`
  [page 213] Start a slave node at Host called Name@Host and passes Args to new node
- `start_link(Host, Name, Args)`
  [page 213] Start a slave node at Host called Name@Host
- `stop(Node)`
  [page 214] Stop (kill) a node
- `pseudo([Master | ServerList])`  
  [page 214] Start a number of pseudo servers
- `pseudo(Master, ServerList)`  
  [page 214] Start a number of pseudo servers
- `relay(Pid)`
  [page 214] Run a pseudo server

sofs

The following functions are exported:

- `a_function(Tuples [, Type]) -> Function`
  [page 218] Create a function.
- `canonical_relation(SetOfSets) -> BinRel`
  [page 219] Return the canonical map.
- `composite(Function1, Function2) -> Function3`
  [page 219] Return the composite of two functions.
- `constant_function(Set, AnySet) -> Function`
  [page 219] Create the function that maps each element of a set onto another set.
- `converse(BinRel1) -> BinRel2`
  [page 219] Return the converse of a binary relation.
- `difference(Set1, Set2) -> Set3`
  [page 220] Return the difference of two sets.
- `digraph_to_family(Graph [, Type]) -> Family`
  [page 220] Create a family from a directed graph.
- `domain(BinRel) -> Set`  
  [page 220] Return the domain of a binary relation.

- `drestriction(BinRel1, Set) -> BinRel2`  
  [page 220] Return a restriction of a binary relation.

- `drestriction(SetFun, Set1, Set2) -> Set3`  
  [page 221] Return a restriction of a relation.

- `empty_set() -> Set`  
  [page 221] Return the untyped empty set.

- `family(Tuples [, Type]) -> Family`  
  [page 221] Create a family of subsets.

- `family_difference(Family1, Family2) -> Family3`  
  [page 221] Return the difference of two families.

- `family_domain(Family1) -> Family2`  
  [page 221] Return a family of domains.

- `family_field(Family1) -> Family2`  
  [page 222] Return a family of fields.

- `family_intersection(Family1) -> Family2`  
  [page 222] Return the intersection of a family of sets of sets.

- `family_intersection(Family1, Family2) -> Family3`  
  [page 222] Return the intersection of two families.

- `family_projection(SetFun, Family1) -> Family2`  
  [page 222] Return a family of modified subsets.

- `family_range(Family1) -> Family2`  
  [page 223] Return a family of ranges.

- `family_specification(Fun, Family1) -> Family2`  
  [page 223] Select a subset of a family using a predicate.

- `family_to_digraph(Family [, GraphType]) -> Graph`  
  [page 223] Create a directed graph from a family.

- `family_to_relation(Family) -> BinRel`  
  [page 224] Create a binary relation from a family.

- `family_union(Family1) -> Family2`  
  [page 224] Return the union of a family of sets of sets.

- `family_union(Family1, Family2) -> Family3`  
  [page 224] Return the union of two families.

- `field(BinRel) -> Set`  
  [page 225] Return the field of a binary relation.

- `from_external(ExternalSet, Type) -> AnySet`  
  [page 225] Create a set.

- `from_sets(ListOfSets) -> Set`  
  [page 225] Create a set out of a list of sets.

- `from_sets(TupleOfSets) -> Ordset`  
  [page 225] Create an ordered set out of a tuple of sets.

- `from_term(Term [, Type]) -> AnySet`  
  [page 225] Create a set.

- `image(BinRel, Set1) -> Set2`  
  [page 226] Return the image of a set under a binary relation.
• intersection(SetOfSets) -> Set
  [page 226] Return the intersection of a set of sets.
• intersection(Set1, Set2) -> Set3
  [page 226] Return the intersection of two sets.
• intersection_of_family(Family) -> Set
  [page 227] Return the intersection of a family.
• inverse(Function1) -> Function2
  [page 227] Return the inverse of a function.
• inverse_image(BinRel, Set1) -> Set2
  [page 227] Return the inverse image of a set under a binary relation.
• is_a_function(BinRel) -> Bool
  [page 227] Test for a function.
• is_disjoint(Set1, Set2) -> Bool
  [page 227] Test for disjoint sets.
• is_empty_set(AnySet) -> Bool
  [page 228] Test for an empty set.
• is_equal(AnySet1, AnySet2) -> Bool
  [page 228] Test two sets for equality.
• is_set(AnySet) -> Bool
  [page 228] Test for an unordered set.
• is_sofs_set(Term) -> Bool
  [page 228] Test for an unordered set.
• is_subset(Set1, Set2) -> Bool
  [page 228] Test two sets for subset.
• is_type(Term) -> Bool
  [page 228] Test for a type.
• join(Relation1, I, Relation2, J) -> Relation3
  [page 228] Return the join of two relations.
• multiple_relative_product(TupleOfBinRels, BinRel1) -> BinRel2
  [page 229] Return the multiple relative product of a tuple of binary relations and a relation.
• no_elements(ASet) -> NoElements
  [page 229] Return the number of elements of a set.
• partition(SetOfSets) -> Partition
  [page 229] Return the coarsest partition given a set of sets.
• partition(SetFun, Set) -> Partition
  [page 229] Return a partition of a set.
• partition_family(SetFun, Set) -> Family
  [page 230] Return a family indexing a partition.
• product(TupleOfSets) -> Relation
• product(Set1, Set2) -> BinRel
• projection(SetFun, Set1) -> Set2
  [page 231] Return a set of substituted elements.
• range(BinRel) -> Set
  [page 231] Return the range of a binary relation.
- `relation(Tuples [, Type])` -> Relation  
  [page 231] Create a relation.
- `relation_to_family(BinRel)` -> Family  
  [page 231] Create a family from a binary relation.
- `relative_product(TupleOfBinRels [, BinRel1])` -> BinRel2  
  [page 232] Return the relative product of a tuple of binary relations and a binary relation.
- `relative_product(BinRel1, BinRel2)` -> BinRel3  
  [page 232] Return the relative product of two binary relations.
- `relative_product1(BinRel1, BinRel2)` -> BinRel3  
  [page 232] Return the relative product of two binary relations.
- `restriction(BinRel1, Set)` -> BinRel2  
  [page 232] Return a restriction of a binary relation.
- `restriction(SetFun, Set1, Set2)` -> Set3  
  [page 233] Return a restriction of a set.
- `set(Terms [, Type])` -> Set  
  [page 233] Create a set of atoms.
- `specification(Fun, Set1)` -> Set2  
  [page 233] Select a subset using a predicate.
- `strict_relation(BinRel1)` -> BinRel2  
  [page 234] Return the strict relation corresponding to a given relation.
- `substitution(SetFun, Set1)` -> Set2  
  [page 234] Return a function with a given set as domain.
- `symdiff(Set1, Set2)` -> Set3  
  [page 235] Return the symmetric difference of two sets.
- `symmetric_partition(Set1, Set2)` -> {Set3, Set4, Set5}  
  [page 235] Return a partition of two sets.
- `to_external(AnySet)` -> ExternalSet  
  [page 235] Return the elements of a set.
- `to_sets(ASet)` -> Sets  
  [page 235] Return a list or a tuple of the elements of set.
- `type(AnySet)` -> Type  
  [page 235] Return the type of a set.
- `union(SetOfSets)` -> Set  
  [page 235] Return the union of a set of sets.
- `union(Set1, Set2)` -> Set3  
  [page 235] Return the union of two sets.
- `union_of_family(Family)` -> Set  
  [page 236] Return the union of a family.
- `weak_relation(BinRel1)` -> BinRel2  
  [page 236] Return the weak relation corresponding to a given relation.

**string**

The following functions are exported:
- `len(String) -> Length`
  [page 237] Return the length of a string
- `equal(String1, String2) -> bool()`
  [page 237] Test string equality
- `concat(String1, String2) -> String3`
  [page 237] Concatenate two strings
- `chr(String, Character) -> Index`
  [page 237] Return the index of the first/last occurrence of Character in String
- `rchr(String, Character) -> Index`
  [page 237] Return the index of the first/last occurrence of Character in String
- `str(String, SubString) -> Index`
  [page 237] Find the index of a substring
- `rstr(String, SubString) -> Index`
  [page 237] Find the index of a substring
- `span(String, Chars) -> Length`
  [page 238] Span characters at start of string
- `cspan(String, Chars) -> Length`
  [page 238] Span characters at start of string
- `substr(String, Start) -> SubString`
  [page 238] Return a substring of String
- `substr(String, Start, Length) -> Substring`
  [page 238] Return a substring of String
- `tokens(String, SeparatorList) -> Tokens`
  [page 238] Split string into tokens
- `chars(Character, Number) -> String`
  [page 238] Returns a string consisting of numbers of characters
- `chars(Character, Number, Tail) -> String`
  [page 238] Returns a string consisting of numbers of characters
- `copies(String, Number) -> Copies`
  [page 239] Copy a string
- `words(String) -> Count`
  [page 239] Count blank separated words
- `words(String, Character) -> Count`
  [page 239] Count blank separated words
- `sub_word(String, Number) -> Word`
  [page 239] Extract subword
- `sub_word(String, Number, Character) -> Word`
  [page 239] Extract subword
- `strip(String) -> Stripped`
  [page 239] Strip leading or trailing characters
- `strip(String, Direction) -> Stripped`
  [page 239] Strip leading or trailing characters
- `strip(String, Direction, Character) -> Stripped`
  [page 239] Strip leading or trailing characters
- `left(String, Number) -> Left`
  [page 240] Adjust left end of string
• `left(String, Number, Character) -> Left`
  [page 240] Adjust left end of string

• `right(String, Number) -> Right`
  [page 240] Adjust right end of string

• `right(String, Number, Character) -> Right`
  [page 240] Adjust right end of string

• `centre(String, Number) -> Centered`
  [page 240] Center a string

• `centre(String, Number, Character) -> Centered`
  [page 240] Center a string

• `sub_string(String, Start) -> SubString`
  [page 240] Extract a substring

• `sub_string(String, Start, Stop) -> SubString`
  [page 241] Extract a substring

### supervisor

The following functions are exported:

• `start_link(Module, Args) -> Result`
  [page 244] Create a supervisor process.

• `start_link(SupName, Module, Args) -> Result`
  [page 244] Create a supervisor process.

• `start_child(SupRef, ChildSpec) -> Result`
  [page 244] Dynamically add a child process to a supervisor.

• `terminate_child(SupRef, Id) -> Result`
  [page 245] Terminate a child process belonging to a supervisor.

• `delete_child(SupRef, Id) -> Result`
  [page 246] Delete a child specification from a supervisor.

• `restart_child(SupRef, Id) -> Result`
  [page 246] Restart a terminated child process belonging to a supervisor.

• `which_children(SupRef) -> [{Id, Child, Type, Modules}]`
  [page 247] Return information about all children specifications and child processes belonging to a supervisor.

• `check_childspecs([ChildSpec]) -> Result`
  [page 247] Check if child specifications are syntactically correct.

• `Module:init(Args) -> Result`
  [page 248] Return a supervisor specification.

### supervisor_bridge

The following functions are exported:

• `start_link(Module, Args) -> Result`
  [page 249] Create a supervisor bridge process.

• `start_link(SupBridgeName, Module, Args) -> Result`
  [page 249] Create a supervisor bridge process.
- Module:init(Args) -> Result
  [page 250] Initialize process and start subsystem.
- Module:terminate(Reason, State)
  [page 250] Clean up and stop subsystem.

SYS

The following functions are exported:

- log(Name,Flag)
  [page 253] Log system events in memory
- log(Name,Flag,Timeout) -> ok | {ok, [system_event()]}  
  [page 253] Log system events in memory
- log_to_file(Name,Flag)
  [page 253] Log system events to the specified file
- log_to_file(Name,Flag,Timeout) -> ok | {error, open_file}
  [page 253] Log system events to the specified file
- statistics(Name,Flag)
  [page 253] Enable or disable the collections of statistics
- statistics(Name,Flag,Timeout) -> ok | {ok, Statistics}
  [page 253] Enable or disable the collections of statistics
- trace(Name,Flag)
  [page 254] Print all system events on standard_io
- trace(Name,Flag,Timeout) -> void()
  [page 254] Print all system events on standard_io
- no_debug(Name)
  [page 254] Turn off debugging
- no_debug(Name,Timeout) -> void()
  [page 254] Turn off debugging
- suspend(Name)
  [page 254] Suspend the process
- suspend(Name,Timeout) -> void()
  [page 254] Suspend the process
- resume(Name)
  [page 254] Resume a suspended process
- resume(Name,Timeout) -> void()
  [page 254] Resume a suspended process
- change_code(Name, Module, OldVsn, Extra)
  [page 254] Send the code change system message to the process
- change_code(Name, Module, OldVsn, Extra, Timeout) -> ok | {error, Reason}
  [page 254] Send the code change system message to the process
- get_status(Name)
  [page 254] Get the status of the process
- get_status(Name,Timeout) -> {status, Pid, {module, Mod}, [PDict, SysState, Parent, Dbg, Misc]}
  [page 254] Get the status of the process
install(Name, Func, FuncState)
  [page 255] Install a debug function in the process
install(Name, Func, FuncState, Timeout)
  [page 255] Install a debug function in the process
remove(Name, Func)
  [page 255] Remove a debug function from the process
remove(Name, Func, Timeout) -> void()
  [page 255] Remove a debug function from the process
debug_options(Options) -> [dbg_opt()]
  [page 256] Convert a list of options to a debug structure
get_debug(Item, Debug, Default) -> term()
  [page 256] Get the data associated with a debug option
handle_debug([dbg_opt()], FormFunc, Extra, Event) -> [dbg_opt()]
  [page 256] Generate a system event
handle_system_msg(Msg, From, Parent, Module, Debug, Misc)
  [page 256] Take care of system messages
print_log(Debug) -> void()
  [page 257] Print the logged events in the debug structure
Mod:system:continue(Parent, Debug, Misc)
  [page 257] Called when the process should continue its execution
Mod:system:terminate(Reason, Parent, Debug, Misc)
  [page 257] Called when the process should terminate
Mod:system:code_change(Misc, Module, OldVsn, Extra) -> {ok, NMisc}
  [page 257] Called when the process should perform a code change

timer

The following functions are exported:

  start() -> ok
  [page 259] Start a global timer server (named timer_server).
  apply_after(Time, Module, Function, Arguments) -> {ok, Tref} | {error, Reason}
  send_after(Time, Pid, Message) -> {ok, TRef} | {error, Reason}
    [page 259] Send Message to Pid after a specified Time.
  send_after(Time, Message) -> {ok, TRef} | {error, Reason}
    [page 259] Send Message to Pid after a specified Time.
  exit_after(Time, Pid, Reason1) -> {ok, TRef} | {error, Reason2}
    [page 260] Send an exit signal with Reason after a specified Time.
  exit_after(Time, Reason1) -> {ok, TRef} | {error, Reason2}
    [page 260] Send an exit signal with Reason after a specified Time.
  kill_after(Time, Pid) -> {ok, TRef} | {error, Reason2}
    [page 260] Send an exit signal with Reason after a specified Time.
  kill_after(Time) -> {ok, TRef} | {error, Reason2}
    [page 260] Send an exit signal with Reason after a specified Time.
• apply_interval(Time, Module, Function, Arguments) -> {ok, TRef} | {error, Reason}

• send_interval(Time, Pid, Message) -> {ok, TRef} | {error, Reason}
  [page 260] Send Message repeatedly at intervals of Time.

• send_interval(Time, Message) -> {ok, TRef} | {error, Reason}
  [page 260] Send Message repeatedly at intervals of Time.

• cancel(TRef) -> {ok, cancel} | {error, Reason}
  [page 260] Cancel a previously requested timeout identified by TRef.

• sleep(Time) -> ok
  [page 260] Suspend the calling process for Time amount of milliseconds.

• tc(Module, Function, Arguments) -> {Time, Value}
  [page 261] Measure the real time it takes to evaluate apply(Module, Function, Arguments)

• seconds(Seconds) -> Milliseconds

• minutes(Minutes) -> Milliseconds
  [page 261] Converts Minutes to Milliseconds.

• hours(Hours) -> Milliseconds
  [page 261] Convert Hours to Milliseconds.

• hms(Hours, Minutes, Seconds) -> Milliseconds
  [page 261] Convert Hours+Minutes+Seconds to Milliseconds.

unix

The following functions are exported:

• cmd(String)
  [page 263] Make a call and return the answer in a list of characters.

win32reg

The following functions are exported:

• change_key(RegHandle, Key) -> ReturnValue
  [page 265] Move to a key in the registry

• change_key_create(RegHandle, Key) -> ReturnValue
  [page 265] Move to a key, create it if it is not there

• close(RegHandle) -> ReturnValue
  [page 265] Close the registry.

• current_key(RegHandle) -> ReturnValue
  [page 265] Return the path to the current key.

• delete_key(RegHandle) -> ReturnValue
  [page 266] Delete the current key

• delete_value(RegHandle, Name) -> ReturnValue
  [page 266] Delete the named value on the current key.
- `expand(String) -> ExpandedString`
  [page 266] Expand a string with environment variables
- `format_error(ErrId) -> ErrorString`
  [page 266] Convert an POSIX errorcode to a string
- `open(OpenModeList) -> ReturnValue`
  [page 266] Open the registry for reading or writing
- `set_value(RegHandle, Name, Value) -> ReturnValue`
  [page 266] Set value at the current registry key with specified name.
- `sub_keys(RegHandle) -> ReturnValue`
  [page 267] Get subkeys to the current key.
- `value(RegHandle, Name) -> ReturnValue`
  [page 267] Get the named value on the current key.
- `values(RegHandle) -> ReturnValue`
  [page 267] Get all values on the current key.
beam_lib

Erlang Module

beam_lib provides an interface to files created by the BEAM compiler (“BEAM files”). The format used, a variant of “EA IFF 1985” Standard for Interchange Format Files, divides data into chunks.

Chunk data can be returned as binaries or as compound terms. Compound terms are returned when chunks are referenced by names (atoms) rather than identifiers (strings). The names recognized and the corresponding identifiers are abstract_code (“Abst”), attributes (“Attr”), exports (“ExpT”), labeled_exports (“ExpT”), imports (“ImpT”), locals (“LocT”), labeled_locals (“LocT”), and atoms (“Atom”).

The syntax of the compound term (ChunkData) is as follows:

- ChunkData = {ChunkId, binary()} | {abstract_code, AbstractCode} | {attributes, [[Attribute, AttributeValue]]} | {exports, [[Function, Arity]]} | {labeled_exports, [[Function, Arity, Label]]} | {imports, [[Module, Function, Arity]]} | {locals, [[Function, Arity]]} | {labeled_locals, [[Function, Arity, Label]]} | {atoms, [[integer()], atom()])

- ChunkRef = ChunkId | ChunkName
- ChunkName = abstract_code | attributes | exports | imports | locals
- ChunkId = string()
- AbstractCode = {AbstVersion, forms()} | no_abstract_code
- AbstVersion = atom()
- Attribute = atom()
- AttributeValue = term()
- Module = Function = atom()
- Arity = integer() >= 0
- Label = integer() >= 0

The list of attributes is sorted on Attribute, and each attribute name occurs once in the list. The attribute values occur in the same order as on the file. The lists of functions are also sorted. It is not checked that the forms conform to the abstract format indicated by AbstVersion.

no_abstract_code means that the “Abst” chunk is present, but empty.

Each of the functions described below accept either a filename or a binary containing a beam module.
Exports

chunks(FileNameOrBinary, [ChunkRef]) -> {ok, {Module, [ChunkData]}} | {error, Module, Reason}

Types:
- FileNameOrBinary = string() | atom() | binary()
- Reason = {unknown_chunk, FileName, atom()} | - see info/1 -

The chunks/2 function reads chunk data for selected chunks. The order of the returned list of chunk data is determined by the order of the list of chunks references; if each chunk data were replaced by the tag, the result would be the given list.

version(FileNameOrBinary) -> {ok, {Module, Version}} | {error, Module, Reason}

Types:
- FileNameOrBinary = string() | atom() | binary()
- Version = [term()]
- Reason = - see chunks/2 -

The version/1 function returns the module version(s) found in a BEAM file.

info(FileNameOrBinary) -> [SourceRef, {module, Module}, {chunks, [ChunkInfo]}] | {error, Module, Reason}

Types:
- FileName = string() | atom()
- FileNameOrBinary = FileName | binary()
- SourceRef = {file, FileName} | {binary, binary()}
- ChunkInfo = {ChunkId, StartPosition, Size}
- StartPosition = integer() > 0
- Size = integer() >= 0
- Reason = {chunk_too_big, FileName, ChunkId, ChunkSize, FileSize} | {invalid_beam_file, FileName, FilePosition} | {invalid_chunk, FileName, ChunkId} | {missing_chunk, FileName, ChunkId} | {not_a_beam_file, FileName} | {file_error, FileName, FileError}

The info/1 function extracts some information about a BEAM file: the file name, the module name, and for each chunk the identifier as well as the position and size in bytes of the chunk data.

cmp(FileNameOrBinary, FileNameOrBinary) -> ok | {error, Module, Reason}

Types:
- FileName = string() | atom()
- FileNameOrBinary = FileName | binary()
- Reason = {modules_different, Module, Module} | {chunks_different, ChunkId} | - see info/1 -
The `cmp/2` function compares the contents of two BEAM files. If the module names are the same, and the chunks with the identifiers "Code", "ExpT", "ImpT", "StrT", and "Atom" have the same contents in both files, `ok` is returned. Otherwise an error message is returned.

`cmp_dirs(Directory1, Directory2) -> {Only1, Only2, Different} | {error, Module, Reason}`

Types:
- `Directory1 = Directory2 = string() | atom()`
- `Different = [{FileName1, FileName2}]`
- `Only1 = Only2 = [FileName]`
- `FileName = FileName1 = FileName2 = string()`
- `Reason = - see info/1 -`

The `cmp_dirs/2` function compares the BEAM files in two directories. Only files with extension ".beam" are compared. BEAM files that exist in directory `Directory1` (`Directory2`) only are returned in `Only1` (`Only2`). BEAM files that exist on both directories but are considered different by `cmp/2` are returned as pairs `{FileName1, FileName2}` where `FileName1` (`FileName2`) exists in directory `Directory1` (`Directory2`).

`diff_dirs(Directory1, Directory2) -> ok | {error, Module, Reason}`

Types:
- `Directory1 = Directory2 = string() | atom()`
- `Reason = - see info/1 -`

The `diff_dirs/2` function compares the BEAM files in two directories the way `cmp_dirs/2` does, but names of files that exist in only one directory or are different are presented on standard output.

`strip(FileOrBinary) -> {ok, [Module, FileOrBinary]} | {error, Module, Reason}`

Types:
- `FileOrBinary = string() | atom()`
- `Reason = - see info/1 -`

The `strip/1` function removes all chunks from a BEAM file except those needed by the loader. In particular, the abstract code is removed. The module name found in the file and the file name, possibly with the ".beam" extension added, are returned.

`strip_files(Files) -> {ok, [[Module, FileOrBinary]]} | {error, Module, Reason}`

Types:
- `Files = [FileOrBinary]`
- `FileOrBinary = string() | atom()`
- `Reason = - see info/1 -`
The `strip_files/1` function removes all chunks except those needed by the loader from BEAM files. In particular, the abstract code is removed. The returned list contains one element for each given file name, ordered as the given list. The list element is a pair of the module name found in the file and the file name, the latter possibly with the "beam" extension added.

```erlang
strip_release(Directory) -> {ok, [{Module, FileName}]} | {error, Module, Reason}
```

**Types:**
- `Directory` = string() | atom()
- `FileName` = string()
- `Reason` = - see `info/1` -

The `strip_release/1` function removes all chunks except those needed by the loader from the BEAM files of a release. `Directory` should be the installation root directory. For example, the current OTP release can be stripped with the call `beam_lib:strip_release(code:root_dir())`. The returned list contains module names and file names of stripped files.

```erlang
format_error(Error) -> character_list()
```

Given the error returned by any function in this module, the function `format_error` returns a descriptive string of the error in English. For file errors, the function `format_error/1` in the `file` module is called.
C

Erlang Module

The c module enables users to enter the short form of some commonly used commands. These functions are intended for interactive use in the Erlang shell.

Exports

bt(Pid) -> void()

Types:
• Pid = pid()
This function evaluates `erlang:process_display(Pid, backtrace)`.

`c(File) -> CompileResult`

This function is equivalent to:
`compile:file(File,[report_errors, report_warnings])`

`c(File, Flags) -> CompileResult`

Types:
• File = atom() | string()
• CompileResult = {ok, ModuleName} | error
• ModuleName = atom()
• Flags = [Flag]
This function calls the following function and then purges and loads the code for the file:
`compile:file(File, Flags ++ [report_errors, report_warnings])`

If the module corresponding to File is being interpreted, then `int:i` is called with the same arguments and the module is loaded into the interpreter. Note that `int:i` only recognizes a subset of the options recognized by `compile:file`.

Extreme care should be exercised when using this command to change running code which is executing. The expected result may not be obtained.
Refer to compiler manual pages for a description of the individual compiler flags.

cd(Dir) -> void()

Types:
• Dir = atom() | string()
This function changes the current working directory to Dir, and then prints the new working directory.

flush() -> void()
This function flushes all messages in the shell message queue.

help() -> void()
This function displays help about the shell and about the command interface module.

i() -> void()
This function provides information about the current state of the system. This call uses the BIFs processes() and process_info/1 to examine the current state of the system. (The code is a good introduction to these two BIFs).

i(X, Y, Z) -> void()
Types:
  • X = Y = Z = int()
This function evaluates process_info(pid(X, Y, Z)).

l(Module) -> void()
Types:
  • Module = atom() | string()
This function evaluates code:purge(Module) followed by code:load_module(Module). It reloads the module.

lc(ListOfFiles) -> Result
Types:
  • ListOfFiles = [File]
  • File = atom() | string()
  • Result = [CompileResult]
  • CompileResult = {ok, ModuleName} | error
  • ModuleName = atom()
This function compiles several files by calling c(File) for each file in ListOfFiles.

ls() -> void()
This function lists all files in the current directory.

ls(Dir) -> void()
Types:
  • Dir = atom() | string()
This function lists all files in the directory Dir.

m() -> void()
This function lists the modules which have been loaded and the files from which they have been loaded.

\[ m(Module) -> void() \]

Types:
- Module = atom()

This function lists information about Module.

\[ memory() -> TupleList \]

Types:
- TupleList = [TwoTuple]
  - TwoTuple = {atom(), int()}

A list of tuples is returned. Each tuple has two elements. The first element is an atom describing memory type. The second element is memory size in bytes. A description of each tuple follows:

- total: The total amount of allocated memory. total is the sum of processes and system.
  - Observe that this is not a complete list of allocated memory; but, it is almost complete.
- processes: The total amount of memory allocated by the processes.
- system: The total amount of memory allocated by the system. Memory allocated by processes is not included.
  - Observe that this is not a complete list of memory allocated by the system; but, it is almost complete.
- atom: The total amount of memory allocated for atoms.
  - This memory is part of the memory presented as system memory.
- atom_used: The total amount of memory actually used for atoms.
  - This memory is part of the memory presented as atom memory.
- binary: The total amount of memory allocated for binaries.
  - This memory is part of the memory presented as system memory.
- code: The total amount of memory allocated for code.
  - This memory is part of the memory presented as system memory.
- ets: The total amount of memory allocated for ets tables.
  - This memory is part of the memory presented as system memory.
- maximum: The maximum total amount of memory allocated since the Erlang runtime system was started.
  - This tuple is only present when the Erlang runtime system is run instrumented.

A process executing this function may be preempted by other processes; therefore, the returned information may not be a consistent snapshot of the memory allocation state. The total and system values are more accurate when the Erlang runtime system is run instrumented.

More tuples in the returned list may be added in the future.

\[ memory(MemoryType) -> int() \]
Types:

- MemoryType = atom()

MemoryType is one of the following atoms: total, processes, system, atom, atom_used, binary, code, ets, or maximum. These atoms correspond to the atoms described for memory/0 above. The amount of memory in bytes that corresponds to the argument is returned.

A process executing this function may be preempted by other processes; therefore, the returned information may not be a consistent snapshot of the memory allocation state.

The total and system values are more accurate when the Erlang runtime system is run instrumented.

More arguments may be added in the future.

Failure: badarg if MemoryType isn't one of the atoms listed above, or if the Erlang runtime system isn't run instrumented and MemoryType is maximum.

nc(File) -> void()

Types:

- File = atom() | string()

This function compiles File and loads it on all nodes in an Erlang nodes network.

nc(File, Flags) -> void()

Types:

- File = atom() | string()
- Flags = [Flag]

This function compiles File with the additional compiler flags Flags and loads it on all nodes in an Erlang nodes network. Refer to the compile manual pages for a description of Flags.

ni() -> void()

This function does the same as i(), but for all nodes in the network.

nl(Module) -> void()

Types:

- Module = atom()

This function loads Module on all nodes in an Erlang nodes network.

nregs() -> void()

This function is the same as regs(), but on all nodes in the system.

pid(X, Y, Z) -> pid()

Types:

- X = Y = Z = int()

This function converts the integers X, Y, and Z to the Pid <X, Y, Z>. It saves typing and the use of list_to_pid/1. This function should only be used when debugging.
pwd() -> void()

This function prints the current working directory.

q() -> void()

This function is shorthand for \texttt{init:stop()}, i.e., it causes the node to stop in a controlled fashion.

regs() -> void()

This function displays formatted information about all registered processes in the system.

\texttt{xm(ModSpec)} -> void()

Types:
- \texttt{ModSpec = Module | File}
- \texttt{Module = atom()}
- \texttt{File = string()}

This function finds undefined functions and unused functions in a module by calling \texttt{xref:m/1}.

zi() -> void()

This function works like \texttt{i()}, but additionally displays information about zombie processes, i.e., processes which have exited, but which are still kept in the system to be inspected.

See Also

\texttt{instrument(3)}
This module provides computation of local and universal time, day-of-the-week, and several time conversion functions.

Time is local when it is adjusted in accordance with the current time zone and daylight saving. Time is universal when it reflects the time at longitude zero, without any adjustment for daylight saving. Universal Coordinated Time (UTC) time is also called Greenwich Mean Time (GMT).

The time functions `local_time/0` and `universal_time/0` provided in this module both return date and time. The reason for this is that separate functions for date and time may result in a date/time combination which is displaced by 24 hours. This happens if one of the functions is called before midnight, and the other after midnight. This problem also applies to the Erlang BIFs `date/0` and `time/0`, and their use is strongly discouraged if a reliable date/time stamp is required.

All dates conform to the Gregorian calendar. This calendar was introduced by Pope Gregory XIII in 1582 and was used in all Catholic countries from this year. Protestant parts of Germany and the Netherlands adopted it in 1698, England followed in 1752, and Russia in 1918 (the October revolution of 1917 took place in November according to the Gregorian calendar).

The Gregorian calendar in this module is extended back to year 0. For a given date, the gregorian days is the number of days up to and including the date specified. Similarly, the gregorian seconds for a given date and time, is the number of seconds up to and including the specified date and time.

For computing differences between epochs in time, use the functions counting gregorian days or seconds. If epochs are given as local time, they must be converted to universal time, in order to get the correct value of the elapsed time between epochs. Use of the function `time_difference/2` is discouraged.

**Exports**

```erlang
date_to_gregorian_days(Year, Month, Day) -> Days
date_to_gregorian_days(Date) -> Days
```

**Types:**
- `Date = {Year, Month, Day}`
- `Year = Month = Day = Days = int()`

This function computes the number of gregorian days starting with year 0 and ending at the given date.

```erlang
datetime_to_gregorian_seconds(DateTime) -> Days
```
Types:
- `DateTime = {date(), time()}`
- `date() = {Year, Month, Day}`
- `time() = {Hour, Minute, Second}
- `Year = Month = Day = Hour = Minute = Second = Days = int()`

This function computes the number of gregorian seconds starting with year 0 and ending at the given date and time.

day_of_the_week(Date) -> DayNumber
day_of_the_week(Year, Month, Day) -> DayNumber

Types:
- `Date = {Year, Month, Day}`
- `Year = Month = Day = DayNumber = int()`

This function computes the day of the week given Year, Month and Day. The return value denotes the day of the week as follows:
- Monday = 1, Tuesday = 2, ..., Sunday = 7
- Year cannot be abbreviated and a value of 93 denotes the year 93, and not the year 1993.
- Month is the month number with January = 1.
- Day is an integer in the range 1 and the number of days in the month Month of the year Year.

gregorian_days_to_date(Days) -> Date

Types:
- `Date = {Year, Month, Day}`
- `Year = Month = Day = Days = int()`

This function computes the date given the number of gregorian days.

gregorian_seconds_to_datetime(Secs) -> DateTime

Types:
- `DateTime = {date(), time()}`
- `date() = {Year, Month, Day}`
- `time() = {Hour, Minute, Second}`
- `Year = Month = Day = Hour = Minute = Second = Days = int()`

This function computes the date and time from the given number of gregorian seconds.

is_leap_year(Year) -> bool()

Types:
- `Year = int()`

This function checks if a year is a leap year.

last_day_of_the_month(Year, Month) -> int()

Types:
- `Year = Month = int()`
This function computes the number of days in a month.

```erlang
local_time() -> {Date, Time}
```

**Types:**
- `Date` = (Year, Month, Day)
- `Time` = (Hour, Minute, Second)
- `Year` = Month = Day = Hour = Minute = Second = int()

This function returns the local time reported by the underlying operating system.

```erlang
local_time_to_universal_time(Date, Time) -> {Date, Time}
```

**Types:**
- `Date` = (Year, Month, Day)
- `Time` = (Hour, Minute, Second)
- `Year` = Month = Day = Hour = Minute = Second = int()

This function converts from local time to Universal Coordinated Time (UTC). Date must refer to a local date after Jan 1, 1970.

```erlang
now_to_local_time(Now) -> {Date, Time}
```

**Types:**
- `Now` = (MegaSecs, Secs, MicroSecs)
- `Date` = (Year, Month, Day)
- `Time` = (Hour, Minute, Second)
- `MegaSecs` = Secs = MilliSecs = int()
- `Year` = Month = Day = Hour = Minute = Second = int()

This function returns local date and time converted from the return value from `erlang:now()`.

```erlang
now_to_universal_time(Now) -> {Date, Time}
now_to_datetime(Now) -> {Date, Time}
```

**Types:**
- `Now` = (MegaSecs, Secs, MicroSecs)
- `Date` = (Year, Month, Day)
- `Time` = (Hour, Minute, Second)
- `MegaSecs` = Secs = MilliSecs = int()
- `Year` = Month = Day = Hour = Minute = Second = int()

This function returns Universal Coordinated Time (UTC) converted from the return value from `erlang:now()`.

```erlang
seconds_to_daytime(Secs) -> {Days, Time}
```

**Types:**
- `Time()` = (Hour, Minute, Second)
- `Hour` = `Minute` = `Second` = `Days` = int()
This function transforms a given number of seconds into days, hours, minutes, and seconds. The Time part is always non-negative, but Days is negative if the argument Secs is.

seconds_to_time(Secs) -> Time

Types:
- Time() = {Hour, Minute, Second}
- Hour = Minute = Second = Secs = int()

This function computes the time from the given number of seconds. Secs must be less than the number of seconds per day.

time_difference(T1, T2) -> Tdiff

Types:
- T1 = T2 = {Date, Time}
- Tdiff = {Day, {Hour, Minute, Second}}
- Date = {Year, Month, Day}
- Time = {Hour, Minute, Second}
- Year = Month = Day = Hour = Minute = Second = int()

This function returns the difference between two {Date, Time} structures. T2 should refer to an epoch later than T1.

This function is obsolete. Use the conversion functions for gregorian days and seconds instead.

time_to_seconds(Time) -> Secs

Types:
- Time() = {Hour, Minute, Second}
- Hour = Minute = Second = Secs = int()

This function computes the number of seconds since midnight up to the specified time.

universal_time() -> {Date, Time}

Types:
- Date = {Year, Month, Day}
- Time = {Hour, Minute, Second}
- Year = Month = Day = Hour = Minute = Second = int()

This function returns the Universal Coordinated Time (UTC) reported by the underlying operating system. Local time is returned if universal time is not available.

universal_time_to_local_time({Date, Time}) -> {Date, Time}

Types:
- Date = {Year, Month, Day}
- Time = {Hour, Minute, Second}
- Year = Month = Day = Hour = Minute = Second = int()
This function converts from Universal Coordinated Time (UTC) to local time. Date must refer to a date after Jan 1, 1970.

valid_date(Date) -> bool()
valid_date(Year, Month, Day) -> bool()

Types:
- Date = {Year, Month, Day}
- Year = Month = Day = int()

This function checks if a date is valid.

Leap Years

The notion that every fourth year is a leap year is not completely true. By the Gregorian rule, a year \( Y \) is a leap year if either of the following rules is valid:

- \( Y \) is divisible by 4, but not by 100; or
- \( Y \) is divisible by 400.

Accordingly, 1996 is a leap year, 1900 is not, but 2000 is.

Date and Time Source

Local time is obtained from the Erlang BIF \texttt{localtime/0}. Universal time is computed from the BIF \texttt{universaltime/0}.

The following facts apply:

- there are 86400 seconds in a day
- there are 365 days in an ordinary year
- there are 366 days in a leap year
- there are 1461 days in a 4 year period
- there are 36524 days in a 100 year period
- there are 146097 days in a 400 year period
- there are 719528 days between Jan 1, 0 and Jan 1, 1970.
dets

Erlang Module

The module dets provides a term storage on file. The stored terms, in this module called objects, are tuples such that one element is defined to be the key. A Dets table is a collection of objects with the key at the same position stored on a file.

Dets is used by the Mnesia application, and is provided as is for users who are interested in an efficient storage of Erlang terms on disk only. Many applications just need to store some terms in a file. Mnesia adds transactions, queries, and distribution.

There are three types of Dets tables: set, bag and duplicate bag. A table of type set has at most one object with a given key. If an object with a key already present in the table is inserted, the existing object is overwritten by the new object. A table of type bag has zero or more different objects with a given key. A table of type duplicate bag has zero or more possibly equal objects with a given key.

Dets tables must be opened before they can be updated or read, and when finished they must be properly closed. If a table has not been properly closed, Dets will automatically repair the table. This can take a substantial time if the table is large. A Dets table is closed when the process which opened the table terminates. If several Erlang processes (users) open the same Dets table, they will share the table. The table is properly closed when all users have either terminated or closed the table. Dets tables are not properly closed if the Erlang runtime system is terminated abnormally.

Note:
A ^C command abnormally terminates an Erlang runtime system in a Unix environment with a break-handler.

Since all operations performed by Dets are disk operations, it is important to realize that a single look-up operation involves a series of disk seek and read operations. For this reason, the Dets functions are much slower than the corresponding Ets functions, although Dets exports a similar interface.

Dets organizes data as a linear hash list and the hash list grows gracefully as more data is inserted into the table. Space management on the file is performed by what is called a buddy system. The current implementation keeps the entire buddy system in RAM, which implies that if the table gets heavily fragmented, quite some memory can be used up. The only way to defragment a table is to close it and then open it again with the repair option set to force.

It is worth noting that the ordered_set type present in Ets is not yet implemented by Dets, neither is the limited support for concurrent updates which makes a sequence of first and next calls safe to use on fixed Ets tables. Both these features will be implemented by Dets in a future release of Erlang/OTP. Until then, the Mnesia application (or some user implemented method for locking) has to be used to
implement safe concurrency. Currently, no library of Erlang/OTP has support for
ordered disk based term storage.

Two versions of the format used for storing objects on file are supported by Dets. The
first version, 8, is the format always used for tables created by OTP R7 and earlier. The
second version, 9, is the default version of tables created by OTP R8 (and later OTP
releases). OTP R8 can create version 8 tables, and convert version 8 tables to version 9,
and vice versa, upon request.

All Dets functions return \{error, Reason\} if an error occurs \(\text{first/1}\) and \(\text{next/2}\) are
exceptions, they exit the process with the error tuple). If given badly formed
arguments, all functions exit the process with a \text{badarg} message.

Types

\[
\begin{align*}
\text{access()} &= \text{read | read\_write} \\
\text{auto\_save()} &= \text{infinity | int()} \\
\text{bindings\_cont()} &= \text{tuple()} \\
\text{bool()} &= \text{true | false} \\
\text{file()} &= \text{string()} \\
\text{int()} &= \text{integer()} \geq 0 \\
\text{keypos()} &= \text{integer()} \geq 1 \\
\text{name()} &= \text{atom()} | \text{ref()} \\
\text{no\_slots()} &= \text{integer()} \geq 1 | \text{default} \\
\text{object()} &= \text{tuple()} \\
\text{object\_cont()} &= \text{tuple()} \\
\text{select\_cont()} &= \text{tuple()} \\
\text{type()} &= \text{bag | duplicate\_bag | set} \\
\text{version()} &= 8 | 9 | \text{default}
\end{align*}
\]

Exports

\text{all()} -> [\text{Name}]

Types:
\begin{itemize}
  \item \text{Name} = \text{name()}
\end{itemize}

Returns a list of the names of all open tables on this node.

\text{close(Name)} -> \text{ok} | \{\text{error, Reason}\}

Types:
\begin{itemize}
  \item \text{Name} = \text{name()}
\end{itemize}

Closes a table. Only processes that have opened a table are allowed to close it.

All open tables must be closed before the system is stopped. If an attempt is made to
open a table which has not been properly closed, Dets automatically tries to repair the
table.

\text{delete(Name, Key)} -> \text{ok} | \{\text{error, Reason}\}

Types:
\begin{itemize}
  \item \text{Name} = \text{name()}
\end{itemize}
Deletes all objects with the key **Key** from the table **Name**.

```prolog
delete_all_objects(Name) -\( \rightarrow \) ok | \{ error, Reason \}
```

Types:
- **Name** = name()

Deletes all objects from a table in almost constant time.

```prolog
delete_object(Name, Object) -\( \rightarrow \) ok | \{ error, Reason \}
```

Types:
- **Name** = name()
- **Object** = object()

Deletes all instances of a given object from a table. If a table is of type `bag` or `duplicate_bag`, the `delete/2` function cannot be used to delete only some of the objects with a given key. This function makes this possible.

```prolog
first(Name) -\( \rightarrow \) Key | \$end_of_table\`
```

Types:
- **Key** = term()
- **Name** = name()

Returns the first key stored in the table **Name** according to the table's internal order, or \$end_of_table\` if the table is empty.

Unless the table is protected using `safe_fixtable/2`, subsequent calls to `next/2` may not work as expected if concurrent updates are made to the table.

Should an error occur, the process is exited with an error tuple \{error, Reason\}. The reason for not returning the error tuple is that it cannot be distinguished from a key.

There are two reasons why `first/1` and `next/2` should not be used: they are not very efficient, and they prevent the use of the key \$end_of_table\` since this atom is used to indicate the end of the table. If possible, the `match`, `match_object`, and `select` functions should be used for traversing tables.

```prolog
foldl(Function, Acc0, Name) -\( \rightarrow \) Acc1 | \{ error, Reason \}
```

Types:
- **Function** = fun(Object, AccIn) -\( \rightarrow \) AccOut
- **Acc0** = Acc1 = AccIn = AccOut = term()
- **Name** = name()
- **Object** = object()

Calls `Function` on successive elements of the table **Name** together with an extra argument `AccIn`. The order in which the elements of the table are traversed is unspecified. `Function` must return a new accumulator which is passed to the next call. `Acc0` is returned if the table is empty.

```prolog
foldr(Function, Acc0, Name) -\( \rightarrow \) Acc1 | \{ error, Reason \}
```

Types:
- **Function** = fun(Object, AccIn) -\( \rightarrow \) AccOut
Calls Function on successive elements of the table Name together with an extra argument AccIn. The order in which the elements of the table are traversed is unspecified. Function must return a new accumulator which is passed to the next call. Acc0 is returned if the table is empty.

\[
\text{from\_ets(Name, EtsTab) \rightarrow ok | \{error, Reason\}}
\]

Types:
- Name = name()
- EtsTab = - see ets(3) -

Replaces the objects of the table Name with the objects of the Ets table EtsTab. The order in which the objects are inserted is not specified. Since ets:safe\_fixtable/2 is called, the Ets table must be public or owned by the calling process.

\[
\text{info(Name) \rightarrow InfoList | undefined}
\]

Types:
- Name = name()
- InfoList = [{Item, Value}]

Returns information about the table Name as a list of \{Item, Value\} tuples:

- \{file\_size, int\}(), the size of the file in bytes.
- \{filename, file\}(), the name of the file where objects are stored.
- \{keypos, keypos\}(), the position of the key.
- \{size, int\}(), the number of objects stored in the table.
- \{type, type\}(), the type of the table.

\[
\text{info(Name, Item) \rightarrow Value | undefined}
\]

Types:
- Name = name()

Returns the information associated with Item for the table Name. In addition to the \{Item, Value\} pairs defined for info/1, the following items are allowed:

- \{access, access\}(), the access mode.
- \{auto\_save, auto\_save\}(), the auto save interval.
- \{hash, Hash\}. Describes which BIF is used to calculate the hash values of the objects stored in the Dets table. Possible values of Hash are hash, which implies that the erlang:hash/2 BIF is used, and phash, which implies that the erlang:phash/2 BIF is used.
- \{memory, int\}(), the size of the file in bytes. The same value is associated with the item file\_size.
- \{no\_keys, int\}(), the number of different keys stored in the table. Only available for version 9 tables.
- \{no\_objects, int\}(), the number of objects stored in the table.
- \{no\_slots, \{Min, Used, Max\}\}, the number of slots of the table. Min is the minimum number of slots, Used is the number of currently used slots, and Max is the maximum number of slots. Only available for version 9 tables.
- \{owner, pid()\}, the pid of the process that handles requests to the Dets table.
- \{ram\_file, bool()\}, whether the table is kept in RAM.
- \{safe\_fixed, SafeFixed\}. If the table is fixed, SafeFixed is a tuple \{FixedAtTime, \[[\text{Pid}, \text{RefCount}]\]\}. FixedAtTime is the time when the table was first fixed, and Pid is the pid of the process that fixes the tableRefCount times. There may be any number of processes in the list. If the table is not fixed, SafeFixed is the atom false.
- \{version, int()\}, the version of the format of the table.

\textbf{init}\_table(Name, InitFun) \(-\) \{ok, \{error, Reason\}\}

\textbf{Types:}
- Name = \text{atom()}
- InitFun = fun(\text{Arg}) \(-\) \text{Res}
- Arg = read | close
- Res = \text{end\_of\_input} | \{\text{[object()]}, \text{InitFun}\} | \text{term()}

Replaces the existing objects of the table Name with objects created by calling the input function InitFun, see below. The reason for using this function rather than calling insert/2 is that of efficiency.

When called with the argument \text{read} the function InitFun is assumed to return end\_of\_input when there is no more input, or \{\text{Objects}, \text{Fun}\}, where Objects is a list of objects and Fun is a new input function. Any other value Value is returned as an error \{\text{error}, \{\text{init\_fun}, \text{Value}\}\}. Each input function will be called exactly once and should an error occur, the last function is called with the argument close, the reply of which is ignored.

If the type of the table is set and there is more than one object with a given key, one of the objects is chosen. This is not necessarily the last object with the given key in the sequence of objects returned by the input functions. Extra objects should be avoided, or the file will be unnecessarily fragmented. This holds also for duplicated objects stored in tables of type duplicate\_bag.

\textbf{insert}\_table(Name, Objects) \(-\) \{ok, \{error, Reason\}\}

\textbf{Types:}
- Name = \text{name()}
- Objects = \text{object()} | \text{[object()]} | \text{term()}

Inserts one or more objects into the table Name. If there already exists an object with the same key as some of the given objects and the table type is set, the old object will be replaced.

\textbf{is\_dets\_file}\_table(FileName) \(-\) \{Bool, \{error, Reason\}\}

\textbf{Types:}
- FileName = \text{file()}
- Bool = \text{bool()}

\textbf{init}\_table(Name, InitFun) \(-\) \{ok, \{error, Reason\}\}

\textbf{Types:}
- Name = \text{atom()}
- InitFun = fun(\text{Arg}) \(-\) \text{Res}
- Arg = read | close
- Res = \text{end\_of\_input} | \{\text{[object()]}, \text{InitFun}\} | \text{term()}

Replaces the existing objects of the table Name with objects created by calling the input function InitFun, see below. The reason for using this function rather than calling insert/2 is that of efficiency.

When called with the argument \text{read} the function InitFun is assumed to return end\_of\_input when there is no more input, or \{\text{Objects}, \text{Fun}\}, where Objects is a list of objects and Fun is a new input function. Any other value Value is returned as an error \{\text{error}, \{\text{init\_fun}, \text{Value}\}\}. Each input function will be called exactly once and should an error occur, the last function is called with the argument close, the reply of which is ignored.

If the type of the table is set and there is more than one object with a given key, one of the objects is chosen. This is not necessarily the last object with the given key in the sequence of objects returned by the input functions. Extra objects should be avoided, or the file will be unnecessarily fragmented. This holds also for duplicated objects stored in tables of type duplicate\_bag.

\textbf{insert}\_table(Name, Objects) \(-\) \{ok, \{error, Reason\}\}

\textbf{Types:}
- Name = \text{name()}
- Objects = \text{object()} | \text{[object()]} | \text{term()}

Inserts one or more objects into the table Name. If there already exists an object with the same key as some of the given objects and the table type is set, the old object will be replaced.

\textbf{is\_dets\_file}\_table(FileName) \(-\) \{Bool, \{error, Reason\}\}

\textbf{Types:}
- FileName = \text{file()}
- Bool = \text{bool()}

\textbf{init}\_table(Name, InitFun) \(-\) \{ok, \{error, Reason\}\}

\textbf{Types:}
- Name = \text{atom()}
- InitFun = fun(\text{Arg}) \(-\) \text{Res}
- Arg = read | close
- Res = \text{end\_of\_input} | \{\text{[object()]}, \text{InitFun}\} | \text{term()}

Replaces the existing objects of the table Name with objects created by calling the input function InitFun, see below. The reason for using this function rather than calling insert/2 is that of efficiency.

When called with the argument \text{read} the function InitFun is assumed to return end\_of\_input when there is no more input, or \{\text{Objects}, \text{Fun}\}, where Objects is a list of objects and Fun is a new input function. Any other value Value is returned as an error \{\text{error}, \{\text{init\_fun}, \text{Value}\}\}. Each input function will be called exactly once and should an error occur, the last function is called with the argument close, the reply of which is ignored.

If the type of the table is set and there is more than one object with a given key, one of the objects is chosen. This is not necessarily the last object with the given key in the sequence of objects returned by the input functions. Extra objects should be avoided, or the file will be unnecessarily fragmented. This holds also for duplicated objects stored in tables of type duplicate\_bag.
Returns true if the file FileName is a Dets table, false otherwise.

lookup(Name, Key) -> [Object] | {error, Reason}

Types:
- Key = term()
- Name = name()
- Object = object()

Returns a list of all objects with the key Key stored in the table Name. For example:

2> dets:open_file(abc, [[type, bag]]).
ok,abc
3> dets:insert(abc, {1,2,3}).
ok
4> dets:insert(abc, {1,3,4}).
ok
5> dets:lookup(abc, 1).
[{1,3,4},{1,3,4}]

If the table is of type set, the function returns either the empty list or a list with one object, as there cannot be more than one object with a given key. If the table is of type bag or duplicate_bag, the function returns a list of arbitrary length.

Note that the order of objects returned is unspecified. In particular, the order in which objects were inserted is not reflected.

match(Continuation) -> {[Match], Continuation2} | '$end_of_table' | {error, Reason}

Types:
- Continuation = Continuation2 = bindings_cont()
- Match = [term()]

Matches some objects stored in a table and returns a list of the bindings that match a given pattern in some unspecified order. The table, the pattern, and the number of objects that are matched are all defined by Continuation, which has been returned by a prior call to match/1 or match/3.

When all objects of the table have been matched, '$end_of_table' is returned.

match(Name, Pattern) -> [Match] | {error, Reason}

Types:
- Name = name()
- Pattern = tuple()
- Match = [term()]

Returns for each object of the table Name that matches Pattern a list of bindings in some unspecified order. See ets(3) [page 103] for a description of patterns. If the keypos'th element of Pattern is unbound, all objects of the table are matched. If the keypos'th element is bound, only the objects with the right key are matched.

match(Name, Pattern, N) -> {[Match], Continuation} | '$end_of_table' | {error, Reason}

Types:
Name = name()
Pattern = tuple()
N = default | int()
Match = [term()]
Continuation = bindings_cont()』

Matches some or all objects of the table Name and returns a list of the bindings that match Pattern in some unspecified order. See ets(3) [page 103] for a description of patterns.

A tuple of the bindings and a continuation is returned, unless the table is empty, in which case ‘$end_of_table’ is returned. The continuation is to be used when matching further objects by calling match/1.

If the keypos'th element of Pattern is bound, all objects of the table are matched. If the keypos'th element is unbound, all objects of the table are matched, N objects at a time. The default, indicated by giving N the value default, is to let the number of objects vary depending on the sizes of the objects. If Name is a version 9 table, all objects with the same key are always matched at the same time which implies that more than N objects may sometimes be matched.

The table should always be protected using safe_fixtable/2 before calling match/3, or errors may occur when calling match/1.

match_delete(Name, Pattern) -> N | {error, Reason}

Types:
- Name = name()
- N = int()
- Pattern = tuple()

Deletes all objects that match Pattern from the table Name, and returns the number of deleted objects. See ets(3) [page 103] for a description of patterns.

If the keypos'th element of Pattern is bound, only the objects with the right key are matched.

match_object(Continuation) -> {[Object], Continuation2} | '$end_of_table' | {error, Reason}

Types:
- Continuation = Continuation2 = object_cont()
- Object = object()

Returns a list of some objects stored in a table that match a given pattern in some unspecified order. The table, the pattern, and the number of objects that are matched are all defined by Continuation, which has been returned by a prior call to match_object/1 or match_object/3.

When all objects of the table have been matched, '$end_of_table' is returned.

match_object(Name, Pattern) -> [Object] | {error, Reason}

Types:
- Name = name()
- Pattern = tuple()
- Object = object()
Returns a list of all objects of the table Name that match Pattern in some unspecified order. See ets(3) [page 103] for a description of patterns.

If the keypos'th element of Pattern is unbound, all objects of the table are matched. If the keypos'th element of Pattern is bound, only the objects with the right key are matched.

Using the match object functions for traversing all objects of a table is more efficient than calling first/1 and next/2 or slot/2.

\[
\text{match_object(Name, Pattern, N)} \rightarrow \{[[\text{Object}], \text{Continuation}] \mid \$\text{end\_of\_table} \mid \{\text{error, Reason}\}
\]

Types:
- Name = name()
- Pattern = tuple()
- N = default | int()
- Object = object()
- Continuation = object_cont()

Matches some or all objects stored in the table Name and returns a list of the objects that match Pattern in some unspecified order. See ets(3) [page 103] for a description of patterns.

A list of objects and a continuation is returned, unless the table is empty, in which case \'$\text{end\_of\_table}$' is returned. The continuation is to be used when matching further objects by calling \text{match\_object}/1.

If the keypos'th element of Pattern is bound, all objects of the table are matched. If the keypos'th element is unbound, all objects of the table are matched, N objects at a time. The default, indicated by giving N the value default, is to let the number of objects vary depending on the sizes of the objects. If Name is a version 9 table, all matching objects with the same key are always returned in the same reply which implies that more than N objects may sometimes be returned.

The table should always be protected using \text{safe\_fixtable}/2 before calling \text{match\_object}/3, or errors may occur when calling \text{match\_object}/1.

\[
\text{member(Name, Key)} \rightarrow \text{Bool} \mid \{\text{error, Reason}\}
\]

Types:
- Name = name()
- Key = term()
- Bool = bool()

Works like \text{lookup}/2, but does not return the objects. The function returns true if one or more elements of the table has the key Key, false otherwise.

\[
\text{next(Name, Key1)} \rightarrow \text{Key2} \mid \$\text{end\_of\_table}
\]

Types:
- Name = name()
- Key1 = Key2 = term()
Returns the key following Key1 in the table Name according to the table's internal order, or "$end of table" if there is no next key. Should an error occur, the process is exited with an error tuple \{error, Reason\}. Use first/1 to find the first key in the table.

open_file(Filename) -> \{ok, Reference\} | \{error, Reason\}

Types:
- FileName = file()
- Reference = ref()

Opens an existing table. If the table has not been properly closed, the error \{error, need_repair\} is returned. The returned reference is to be used as the name of the table. This function is most useful for debugging purposes.

open_file(Name, Args) -> \{ok, Name\} | \{error, Reason\}

Types:
- Name = atom()

Opens a table. An empty Dets table is created if no file exists. The atom Name is the name of the table. The table name must be provided in all subsequent operations on the table. The name can be used by other processes as well, and several process can share one table.

If two processes open the same table by giving the same name and arguments, then the table will have two users. If one user closes the table, it still remains open until the second user closes the table.

The Args argument is a list of \{Key, Val\} tuples where the following values are allowed:

- \{access, access()\}. It is possible to open existing tables in read-only mode. A table which is opened in read-only mode is not subjected to the automatic file reparation algorithm if it is later opened after a crash. The default value is read_write.
- \{auto_save, auto_save()\}, the auto save interval. If the interval is an integer Time, the table is flushed to disk whenever it is not accessed for Time milliseconds. A table that has been flushed will require no reparation when reopened after an uncontrolled emulator halt. If the interval is the atom infinity, auto save is disabled. The default value is 180000 (3 minutes).
- \{estimated_no_objects, int()\}. Equivalent to the min_no_slots option.
- \{file, file()\}, the name of the file to be opened. The default value is the name of the table.
- \{max_no_slots, no_slots()\}, the maximum number of slots that will be used. The default value is 2 M, and the maximal value is 32 M. Note that a higher value may increase the fragmentation of the table, and conversely, that a smaller value may decrease the fragmentation, at the expense of execution time. Only available for version 9 tables.
- \{min_no_slots, no_slots()\}. Application performance can be enhanced with this flag by specifying, when the table is created, the estimated number of different keys that will be stored in the table. The default value as well as the minimum value is 256.
- \{keypos, keypos()\}, the position of the element of each object to be used as key. The default value is 1. The ability to explicitly state the key position is most convenient when we want to store Erlang records in which the first position of the record is the name of the record type.

- \{ram_file, bool()\}, whether the table is to be kept in RAM. Keeping the table in RAM may sound like an anomaly, but can enhance the performance of applications which open a table, insert a set of objects, and then close the table. When the table is closed, its contents are written to the disk file. The default value is false.

- \{repair, Value\}. Value can be either a \texttt{bool()} or the atom \texttt{force}. The flag specifies whether the Dets server should invoke the automatic file repair algorithm. The default is \texttt{true}. If \texttt{false} is specified, there is no attempt to repair the file and \{error, need_repair\} is returned if the table needs to be repaired. The value \texttt{force} means that a reparation will take place even if the table has been properly closed. This is how to convert tables created by older versions of STD LIB. An example is tables hashed with the deprecated \texttt{erlang:hash/2} BIF. Tables created with Dets from a STD LIB version of 1.8.2 and later use the new \texttt{erlang:phash/2} function, which is preferred.

- \{type, type()\}, the type of the table. The default value is \texttt{set}.

- \{version, version()\}, the version of the format used for the table. The default value is \texttt{9}. Tables on the format used before OTP R8 can be created by giving the value \texttt{8}. A version 8 table can be converted to a version 9 table by giving the options \{\texttt{version,9} and \{\texttt{repair,force}\}.

\textbf{pid2name(Pid) -&gt; \{ok, Name\} | undefined}

Types:
- Name = name()
- Pid = pid()

Returns the name of the table given the pid of a process that handles requests to a table, or undefined if there is no such table.

This function is meant to be used for debugging only.

\textbf{safe_fixtable(Name, Fix)}

Types:
- Name = name()
- Fix = bool()

If \texttt{Fix} is \texttt{true}, the table \texttt{Name} is fixed (once more) by the calling process, otherwise the table is released. The table is also released when a fixing process terminates.

If several processes fix a table, the table will remain fixed until all processes have released it or terminated. A reference counter is kept on a per process basis, and \texttt{N} consecutive fixes require \texttt{N} releases to release the table.

It is not guaranteed that calls to \texttt{first/1, next/2, select} and match functions work as expected even if the table has been fixed; the limited support for concurrency implemented in Ets has not yet been implementeded in Dets. Fixing a table currently only disables resizing of the hash list of the table.

\textbf{select(Continuation) -&gt; \{Selection, Continuation2\} | \$end_of_table\ | \{error, Reason\}}
Returns the results of applying a match specification to some objects stored in a table. The table, the match specification, and the number of objects that are matched are all defined by Continuation, which has been returned by a prior call to select/1 or select/3.

When all objects of the table have been matched, 'end_of_table' is returned.

select(Name, MatchSpec) -> Selection | {error, Reason}

Returns the results of applying the match specification MatchSpec to all or some objects stored in the table Name. The order of the objects is not specified. See the ERTS User's Guide for a description of match specifications.

If the keypos'th element of MatchSpec is unbound, the match specification is applied to all objects of the table. If the keypos'th element is bound, the match specification is applied to the objects with the right key(s) only.

Using the select functions for traversing all objects of a table is more efficient than calling first/1 and next/2 or slot/2.

select(Name, MatchSpec, N) -> {Selection, Continuation} | 'end_of_table' | {error, Reason}

Returns the results of applying the match specification MatchSpec to some or all objects stored in the table Name. The order of the objects is not specified. See the ERTS User's Guide for a description of match specifications.

A tuple of the results of applying the match specification and a continuation is returned, unless the table is empty, in which case 'end_of_table' is returned. The continuation is to be used when matching further objects by calling select/1.

If the keypos'th element of MatchSpec is bound, the match specification is applied to all objects of the table with the right key(s). If the keypos'th element of MatchSpec is unbound, the match specification is applied to all objects of the table, N objects at a time. The default, indicated by giving N the value default, is to let the number of objects vary depending on the sizes of the objects. If Name is a version 9 table, all objects with the same key are always handled at the same time which implies that the match specification may be applied to more than N objects.

The table should always be protected using safe_fixtable/2 before calling select/3, or errors may occur when calling select/1.
select_delete(Name, MatchSpec) -> N | {error, Reason}

Types:
- Name = name()
- MatchSpec = match_spec()
- N = int()

Deletes each object from the table Name such that applying the match specification MatchSpec to the object returns the value true. See the ERTS User’s Guide for a description of match specifications. Returns the number of deleted objects.

If the keypos’th element of MatchSpec is bound, the match specification is applied to the objects with the right key(s) only.

slot(Name, I) -> ‘$end_of_table’ | [Object] | {error, Reason}

Types:
- Name = name()
- I = int()
- Object = object()

The objects of a table are distributed among slots, starting with slot 0 and ending with slot n. This function returns the list of objects associated with slot I. If I is greater than n ‘$end_of_table’ is returned.

sync(Name) -> ok | {error, Reason}

Types:
- Name = name()

Ensures that all updates made to the table Name are written to disk. This also applies to tables which have been opened with the ram_file flag set to true. In this case, the contents of the RAM file are flushed to disk.

Note that the space management data structures kept in RAM, the buddy system, is also written to the disk. This may take some time if the table is fragmented.

to_ets(Name, EtsTab) -> EtsTab | {error, Reason}

Types:
- Name = name()
- EtsTab = - see ets(3) -

Inserts the objects of the Dets table Name into the Ets table EtsTab. The order in which the objects are inserted is not specified. The existing objects of the Ets table are kept unless overwritten.

traverse(Name, Fun) -> Return | {error, Reason}

Types:
- Fun = fun(Object) -> FunReturn
- FunReturn = continue | {continue, Val} | {done, Value}
- Val = Value = term()
- Name = name()
- Object = object()
Return = [term()]

Applies Fun to each object stored in the table Name in some unspecified order. Different actions are taken depending on the return value of Fun. The following Fun return values are allowed:

continue Continue to perform the traversal. For example, the following function can be used to print out the contents of a table:

fun(X) -> io:format("~p
", [X]), continue end.

{continue, Val} Continue the traversal and accumulate Val. The following function is supplied in order to collect all objects of a table in a list:

fun(X) -> {continue, X} end.

{done, Value} Terminate the traversal and return [Value | Acc].

update_counter(Name, Key, Increment) -> Result

Types:
- Name = name()
- Key = term()
- Increment = (Pos, Incr) | Incr
- Pos = Incr = Result = integer()

Updates the object with key Key stored in the table Name of type set by adding Incr to the element at the Pos:th position. The new counter value is returned. If no position is specified, the element directly following the key is updated.

This functions provides a way of updating a counter, without having to look up an object, update the object by incrementing an element and insert the resulting object into the table again.

See Also

ets(3) [page 103], mnesia(3)
Dict implements a Key-Value dictionary. The representation of a dictionary is not defined.

Exports

append(Key, Value, Dict1) -> Dict2
Types:
- Key = Value = term()
- Dict1 = Dict2 = dictionary()
This function appends a new Value to the current list of values associated with Key. An exception is generated if the initial value associated with Key is not a list of values.

append_list(Key, ValList, Dict1) -> Dict2
Types:
- ValList = [Value]
- Key = Value = [term()]
- Dict1 = Dict2 = dictionary()
This function appends a list of values ValList to the current list of values associated with Key. An exception is generated if the initial value associated with Key is not a list of values.

erase(Key, Dict1) -> Dict2
Types:
- Key = term()
- Dict1 = Dict2 = dictionary()
This function erases all items with a given key from a dictionary.

fetch(Key, Dict) -> Value
Types:
- Key = Value = term()
- Dict = dictionary()
This function returns the value associated with Key in the dictionary Dict. fetch assumes that the Key is present in the dictionary and an exception is generated if Key is not in the dictionary.
fetch_keys(Dict) -> Keys

Types:
- Dict = dictionary()
- Keys = [term()]

This function returns a list of all keys in the dictionary.

filter(Pred, Dict1) -> Dict2

Types:
- Pred = fun(Key, Value) -> bool()
- Dict1 = Dict2 = dictionary()

Dict2 is a dictionary of all keys and values in Dict1 for which Pred(Key, Value) is true.

find(Key, Dict) -> Result

Types:
- Key = term()
- Dict = dictionary()
- Result = {ok, Value} | error

This function searches for a key in a dictionary. Returns {ok, Value} where Value is the value associated with Key, or error if the key is not present in the dictionary.

fold(Function, Acc0, Dict) -> Acc1

Types:
- Function = fun(Key, Value, AccIn) -> AccOut
- Acc0 = Acc1 = AccIn = AccOut = term()
- Dict = dictionary()

Calls Function on successive keys and values of Dict together with an extra argument Acc (short for accumulator). Function must return a new accumulator which is passed to the next call. Acc0 is returned if the list is empty. The evaluation order is undefined.

from_list(List) -> Dict

Types:
- List = [{Key, Value}]
- Dict = dictionary()

This function converts the dictionary to a list representation.

is_key(Key, Dict) -> bool()

Types:
- Key = term()
- Dict = dictionary()

This function tests if Key is contained in the dictionary Dict.

map(Func, Dict1) -> Dict2
Types:
- `Func = fun(Key, Value) -> Value`
- `Dict1 = Dict2 = dictionary()`

`map` calls `Func` on successive keys and values of `Dict` to return a new value for each key. The evaluation order is undefined.

`merge(Func, Dict1, Dict2) -> Dict3`

Types:
- `Func = fun(Key, Value1, Value2) -> Value`
- `Dict1 = Dict2 = Dict3 = dictionary()`

`merge` merges two dictionaries, `Dict1` and `Dict2`, to create a new dictionary. All the Key - Value pairs from both dictionaries are included in the new dictionary. If a key occurs in both dictionaries then `Func` is called with the key and both values to return a new value. `merge` could be defined as:

```
merge(Fun, D1, D2) ->
    fold(fun (K, V1, D) ->
        update(K, fun (V2) -> Fun(K, V1, V2) end, V1, D)
    end, D2, D1).
```

but is faster.

`new() -> dictionary()`

This function creates a new dictionary.

`store(Key, Value, Dict1) -> Dict2`

Types:
- `Key = Value = term()`
- `Dict1 = Dict2 = dictionary()`

This function stores a Key - Value pair in a dictionary. If the Key already exists in `Dict1`, the associated value is replaced by `Value`.

`to_list(Dict) -> List`

Types:
- `Dict = dictionary()`
- `List = [{Key, Value}]`

This function converts the dictionary to a list representation.

`update(Key, Function, Dict) -> Dict`

Types:
- `Key = term()`
- `Function = fun(Value) -> Value`
- `Dict = dictionary()`

Update the a value in a dictionary by calling `Function` on the value to get a new value. An exception is generated if `Key` is not present in the dictionary.
update(Key, Function, Initial, Dict) -> Dict

Types:
- Key = Initial = term()
- Function = fun(Value) -> Value
- Dict = dictionary()

Update the a value in a dictionary by calling Function on the value to get a new value. If Key is not present in the dictionary then Initial will be stored as the first value. For example we could define append/3 as:

```erlang
append(Key, Val, D) ->
    update(Key, fun (Old) -> Old ++ [Val] end, [Val], D).
```

update_counter(Key, Increment, Dict) -> Dict

Types:
- Key = term()
- Increment = number()
- Dict = dictionary()

Add Increment to the value associated with Key and store this value. If Key is not present in the dictionary then Increment will be stored as the first value. This is could have been defined as:

```erlang
update_counter(Key, Incr, D) ->
    update(Key, fun (Old) -> Old + Incr end, Incr, D).
```

but is faster.

Notes

The functions append and append_list are included so we can store keyed values in a list accumulator. For example:

```erlang
> D0 = dict:new(),
D1 = dict:store(files, [], D0),
D2 = dict:append(files, f1, D1),
D3 = dict:append(files, f2, D2),
D4 = dict:append(files, f3, D3),
dict:fetch(files, D4).
[f1,f2,f3]
```

This saves the trouble of first fetching a keyed value, appending a new value to the list of stored values, and storing the result.

The function fetch should be used if the key is known to be in the dictionary, otherwise find.
digraph

Erlang Module

The digraph module implements a version of labeled directed graphs. What makes the graphs implemented here non-proper directed graphs is that multiple edges between vertices are allowed. However, the customary definition of directed graphs will be used in the text that follows.

A directed graph (or just “digraph”) is a pair \((V, E)\) of a finite set \(V\) of vertices and a finite set \(E\) of directed edges (or just “edges”). The set of edges \(E\) is a subset of \(V \times V\) (the Cartesian product of \(V\) with itself). In this module, \(V\) is allowed to be empty; the so obtained unique digraph is called the empty digraph. Both vertices and edges are represented by unique Erlang terms.

Digraphs can be annotated with additional information. Such information may be attached to the vertices and to the edges of the digraph. A digraph which has been annotated is called a labeled digraph, and the information attached to a vertex or an edge is called a label. Labels are Erlang terms.

An edge \(e = (v, w)\) is said to emanate from vertex \(v\) and to be incident on vertex \(w\). The out-degree of a vertex is the number of edges emanating from that vertex. The in-degree of a vertex is the number of edges incident on that vertex. If there is an edge emanating from \(v\) and incident on \(w\), then \(w\) is said to be an out-neighbour of \(v\), and \(v\) is said to be an in-neighbour of \(w\). A path \(P\) from \(v[1]\) to \(v[k]\) in a digraph \((V, E)\) is a non-empty sequence \(v[1], v[2], ..., v[k]\) of vertices in \(V\) such that there is an edge \((v[i], v[i+1])\) in \(E\) for \(1 \leq i < k\). The length of the path \(P\) is \(k-1\). \(P\) is simple if all vertices are distinct, except that the first and the last vertices may be the same. \(P\) is a cycle if the length of \(P\) is not zero and \(v[1] = v[k]\). A loop is a cycle of length one. A simple cycle is a path that is both a cycle and simple. An acyclic digraph is a digraph that has no cycles.

Exports

- `add_edge(G, E, V1, V2, Label) -> edge() | {error, Reason}`
- `add_edge(G, V1, V2, Label) -> edge() | {error, Reason}`
- `add_edge(G, V1, V2) -> edge() | {error, Reason}`

Types:
- \(G = \text{digraph()}\)
- \(E = \text{edge()}\)
- \(V1 = V2 = \text{vertex()}\)
- \(\text{Label} = \text{label()}\)
- \(\text{Reason} = \{\text{bad\_edge}, \text{Path}\} | \{\text{bad\_vertex}, V\}\)
- \(\text{Path} = [\text{vertex()}]\)
add_edge/5 creates (or modifies) the edge \( E \) of the digraph \( G \), using Label as the (new) label [page 74] of the edge. The edge is emanating [page 74] from \( V_1 \) and incident [page 74] on \( V_2 \). Returns \( E \).

\( \text{add_edge}(G, V_1, V_2, \text{Label}) \) is equivalent to \( \text{add_edge}(G, E, V_1, V_2, \text{Label}) \), where \( E \) is a created edge. Tuples on the form \([‘$e’ | N] \), where \( N \) is an integer \( \geq 1 \), are used for representing the created edges.

\( \text{add_edge}(G, V_1, V_2) \) is equivalent to \( \text{add_edge}(G, V_1, V_2, []) \).

If the edge would create a cycle in an acyclic digraph [page 74], then \{error, \{bad_edge, Path\}\} is returned. If either of \( V_1 \) or \( V_2 \) is not a vertex of the digraph \( G \), then \{error, \{bad_vertex, V\}\} is returned, \( V = V_1 \) or \( V = V_2 \).

\( \text{add_vertex}(G, V, \text{Label}) \rightarrow \text{vertex()} \)

\( \text{add_vertex}(G, V) \rightarrow \text{vertex()} \)

\( \text{add_vertex}(G) \rightarrow \text{vertex()} \)

**Types:**

- \( G = \text{digraph()} \)
- \( V = \text{vertex()} \)
- \( \text{Label} = \text{label()} \)

\( \text{add_vertex}/3 \) creates (or modifies) the vertex \( V \) of the digraph \( G \), using Label as the (new) label [page 74] of the vertex. Returns \( V \).

\( \text{add_vertex}(G, V) \) is equivalent to \( \text{add_vertex}(G, V, []) \).

\( \text{add_vertex}/1 \) creates a vertex using the empty list as label, and returns the created vertex. Tuples on the form \([‘$v’ | N] \), where \( N \) is an integer \( \geq 1 \), are used for representing the created vertices.

\( \text{del_edge}(G, E) \rightarrow \text{true} \)

**Types:**

- \( G = \text{digraph()} \)
- \( E = \text{edge()} \)

Deletes the edge \( E \) from the digraph \( G \).

\( \text{del_edges}(G, \text{Edges}) \rightarrow \text{true} \)

**Types:**

- \( G = \text{digraph()} \)
- \( \text{Edges} = \text{[edge()]} \)

Deletes the edges in the list \( \text{Edges} \) from the digraph \( G \).

\( \text{del_path}(G, V_1, V_2) \rightarrow \text{true} \)

**Types:**

- \( G = \text{digraph()} \)
- \( V_1 = V_2 = \text{vertex()} \)
Deletes edges from the digraph \( G \) until there are no paths [page 74] from the vertex \( V_1 \) to the vertex \( V_2 \).

A sketch of the procedure employed: Find an arbitrary simple path [page 74] \( v[1], v[2], \ldots, v[k] \) from \( V_1 \) to \( V_2 \) in \( G \). Remove all edges of \( G \) emanating [page 74] from \( v[i] \) and incident [page 74] to \( v[i+1] \) for \( 1 \leq i < k \) (including multiple edges). Repeat until there is no path between \( V_1 \) and \( V_2 \).

\[
\text{del_vertex}(G, V) \to \text{true}
\]

Types:
- \( G = \text{digraph}() \)
- \( V = \text{vertex}() \)

Deletes the vertex \( V \) from the digraph \( G \). Any edges emanating [page 74] from \( V \) or incident [page 74] on \( V \) are also deleted.

\[
\text{del_vertices}(G, Vertices) \to \text{true}
\]

Types:
- \( G = \text{digraph}() \)
- \( \text{Vertices} = [\text{vertex}()] \)

Deletes the vertices in the list \( \text{Vertices} \) from the digraph \( G \).

\[
\text{delete}(G) \to \text{true}
\]

Types:
- \( G = \text{digraph}() \)

Deletes the digraph \( G \). This call is important because digraphs are implemented with \( \text{Ets} \). There is no garbage collection of \( \text{Ets} \) tables. The digraph will, however, be deleted if the process that created the digraph terminates.

\[
\text{edge}(G, E) \to \{E, V_1, V_2, \text{Label}\} \mid \text{false}
\]

Types:
- \( G = \text{digraph}() \)
- \( E = \text{edge}() \)
- \( V_1, V_2 = \text{vertex}() \)
- \( \text{Label} = \text{label}() \)

Returns \( \{E, V_1, V_2, \text{Label}\} \) where \( \text{Label} \) is the label [page 74] of the edge \( E \) emanating [page 74] from \( V_1 \) and incident [page 74] on \( V_2 \) of the digraph \( G \). If there is no edge \( E \) of the digraph \( G \), then \text{false} is returned.

\[
\text{edges}(G) \to \text{Edges}
\]

Types:
- \( G = \text{digraph}() \)
- \( \text{Edges} = [\text{edge}()] \)

Returns a list of all edges of the digraph \( G \), in some unspecified order.

\[
\text{edges}(G, V) \to \text{Edges}
\]
Types:
- \( G = \text{digraph}() \)
- \( V = \text{vertex}() \)
- \( \text{Edges} = [\text{edge}()] \)

Returns a list of all edges emanating [page 74] from or incident [page 74] on \( V \) of the digraph \( G \), in some unspecified order.

get_cycle(\( G, V \)) \( \rightarrow \) Vertices \| false

Types:
- \( G = \text{digraph}() \)
- \( V1 = V2 = \text{vertex}() \)
- \( \text{Vertices} = [\text{vertex}()] \)

If there is a simple cycle [page 74] of length two or more through the vertex \( V \), then the cycle is returned as a list \([V, \ldots, V]\) of vertices, otherwise if there is a loop [page 74] through \( V \), then the loop is returned as a list \([V]\). If there are no cycles through \( V \), then false is returned.

get_path/3 is used for finding a simple cycle through \( V \).

get_path(\( G, V1, V2 \)) \( \rightarrow \) Vertices \| false

Types:
- \( G = \text{digraph}() \)
- \( V1 = V2 = \text{vertex}() \)
- \( \text{Vertices} = [\text{vertex}()] \)

Tries to find a simple path [page 74] from the vertex \( V1 \) to the vertex \( V2 \) of the digraph \( G \). Returns the path as a list \([V1, \ldots, V2]\) of vertices, or false if no simple path from \( V1 \) to \( V2 \) of length one or more exists.

The digraph \( G \) is traversed in a depth-first manner, and the first path found is returned.

get_short_cycle(\( G, V \)) \( \rightarrow \) Vertices \| false

Types:
- \( G = \text{digraph}() \)
- \( V1 = V2 = \text{vertex}() \)
- \( \text{Vertices} = [\text{vertex}()] \)

Tries to find an as short as possible simple cycle [page 74] through the vertex \( V \) of the digraph \( G \). Returns the cycle as a list \([V, \ldots, V]\) of vertices, or false if no simple cycle through \( V \) exists. Note that a loop [page 74] through \( V \) is returned as the list \([V, V]\).

get_short_path/3 is used for finding a simple cycle through \( V \).

get_short_path(\( G, V1, V2 \)) \( \rightarrow \) Vertices \| false

Types:
- \( G = \text{digraph}() \)
- \( V1 = V2 = \text{vertex}() \)
- \( \text{Vertices} = [\text{vertex}()] \)
Tries to find an as short as possible simple path [page 74] from the vertex \( V_1 \) to the vertex \( V_2 \) of the digraph \( G \). Returns the path as a list \([V_1, \ldots, V_2]\) of vertices, or false if no simple path from \( V_1 \) to \( V_2 \) of length one or more exists.

The digraph \( G \) is traversed in a breadth-first manner, and the first path found is returned.

\[
in\_degree(G, V) \rightarrow \text{integer}()
\]

Types:
- \( G = \text{digraph}() \)
- \( V = \text{vertex}() \)

Returns the in-degree [page 74] of the vertex \( V \) of the digraph \( G \).

\[
in\_edges(G, V) \rightarrow \text{Edges}
\]

Types:
- \( G = \text{digraph}() \)
- \( V = \text{vertex}() \)
- \( \text{Edges} = \text{[edge()]} \)

Returns a list of all edges incident [page 74] on \( V \) of the digraph \( G \), in some unspecified order.

\[
in\_neighbours(G, V) \rightarrow \text{Vertices}
\]

Types:
- \( G = \text{digraph}() \)
- \( V = \text{vertex}() \)
- \( \text{Vertices} = \text{[vertex()]} \)

Returns a list of all in-neighbours [page 74] of \( V \) of the digraph \( G \), in some unspecified order.

\[
\text{info}(G) \rightarrow \text{InfoList}
\]

Types:
- \( G = \text{digraph}() \)
- \( \text{InfoList} = [\{\text{cyclicity, Cyclicity}\}, \{\text{memory, NoWords}\}, \{\text{protection, Protection}\}] \)
- \( \text{Cyclicity} = \text{cyclic} | \text{acyclic} \)
- \( \text{Protection} = \text{public} | \text{protected} | \text{private} \)
- \( \text{NoWords} = \text{integer()} \geq 0 \)

Returns a list of \( \{\text{Tag}, \text{Value}\} \) pairs describing the digraph \( G \). The following pairs are returned:

- \( \{\text{cyclicity, Cyclicity}\} \), where \( \text{Cyclicity} \) is cyclic or acyclic, according to the options given to \text{new}.
- \( \{\text{memory, NoWords}\} \), where \( \text{NoWords} \) is the number of words allocated to the sets tables
- \( \{\text{protection, Protection}\} \), where \( \text{Protection} \) is public, protected or private, according to the options given to \text{new}. 
new() -> digraph()

   Equivalent to new([]).

new(Type) -> digraph() | {error, Reason}

Types:
   • Type = [cyclic | acyclic | public | private | protected]
   • Reason = {unknown_type, term()}

Returns an empty digraph [page 74] with properties according to the options in Type:

   cyclic  Allow cycles [page 74] in the digraph (default).
   acyclic  The digraph is to be kept acyclic [page 74].
   public  The digraph may be read and modified by any process.
   protected  Other processes can only read the digraph (default).
   private  The digraph can be read and modified by the creating process only.

   If an unrecognized type option T is given, then {error, {unknown_type, T}} is returned.

no_edges(G) -> integer() >= 0

Types:
   • G = digraph()

Returns the number of edges of the digraph G.

no_vertices(G) -> integer() >= 0

Types:
   • G = digraph()

Returns the number of vertices of the digraph G.

out_degree(G, V) -> integer()

Types:
   • G = digraph()
   • V = vertex()

Returns the out-degree [page 74] of the vertex V of the digraph G.

out_edges(G, V) -> Edges

Types:
   • G = digraph()
   • V = vertex()
   • Edges = [edge()]

Returns a list of all edges emanating [page 74] from V of the digraph G, in some unspecified order.

out_neighbours(G, V) -> Vertices
Types:
- G = digraph()
- V = vertex()
- Vertices = [vertex()]

Returns a list of all out-neighbours [page 74] of the digraph \( G \), in some unspecified order.

\[
\text{vertex}(G, V) -> \{V, \text{Label}\} | \text{false}
\]

Types:
- G = digraph()
- V = vertex()
- Label = label()

Returns \( \{V, \text{Label}\} \) where \( \text{Label} \) is the label [page 74] of the vertex \( V \) of the digraph \( G \), or false if there is no vertex \( V \) of the digraph \( G \).

\[
\text{vertices}(G) -> \text{Vertices}
\]

Types:
- G = digraph()
- Vertices = [vertex()]

Returns a list of all vertices of the digraph \( G \), in some unspecified order.

digraph_utils

Erlang Module

The digraph_utils module implements some algorithms based on depth-first traversal of directed graphs. See the digraph module for basic functions on directed graphs.

A directed graph (or just "digraph") is a pair (V, E) of a finite set V of vertices and a finite set E of directed edges (or just "edges"). The set of edges E is a subset of V × V (the Cartesian product of V with itself).

Digraphs can be annotated with additional information. Such information may be attached to the vertices and to the edges of the digraph. A digraph which has been annotated is called a labeled digraph, and the information attached to a vertex or an edge is called a label.

An edge e = (v, w) is said to emanate from vertex v and to be incident on vertex w. If there is an edge emanating from v and incident on w, then w is said to be an out-neighbour of v. A path P from v[1] to v[k] in a digraph (V, E) is a non-empty sequence v[1], v[2], ..., v[k] of vertices in V such that there is an edge (v[i],v[i+1]) in E for 1 ≤ i < k. The length of the path P is k-1. P is a cycle if the length of P is not zero and v[1] = v[k]. A loop is a cycle of length one. An acyclic digraph is a digraph that has no cycles.

A depth-first traversal of a directed digraph can be viewed as a process that visits all vertices of the digraph. Initially, all vertices are marked as unvisited. The traversal starts with an arbitrarily chosen vertex, which is marked as visited, and follows an edge to an unmarked vertex, marking that vertex. The search then proceeds from that vertex in the same fashion, until there is no edge leading to an unvisited vertex. At that point the process backtracks, and the traversal continues as long as there are unexamined edges. If there remain unvisited vertices when all edges from the first vertex have been examined, some hitherto unvisited vertex is chosen, and the process is repeated.

A partial ordering of a set S is a transitive, antisymmetric and reflexive relation between the objects of S. The problem of topological sorting is to find a total ordering of S that is a superset of the partial ordering. A digraph G = (V, E) is equivalent to a relation E on V (we neglect the fact that the version of directed graphs implemented in the digraph module allows multiple edges between vertices). If the digraph has no cycles of length two or more, then the reflexive and transitive closure of E is a partial ordering.

A subgraph G' of G is a digraph whose vertices and edges form subsets of the vertices and edges of G. G' is maximal with respect to a property P if all other subgraphs that include the vertices of G' do not have the property P. A strongly connected component is a maximal subgraph such that there is a path between each pair of vertices. A connected component is a maximal subgraph such that there is a path between each pair of vertices, considering all edges undirected.
Exports

components(Digraph) -> [Component]

Types:
- Digraph = digraph()
- Component = [vertex()]

Returns a list of connected components [page 81]. Each component is represented by its vertices. The order of the vertices and the order of the components are arbitrary.
Each vertex of the digraph Digraph occurs in exactly one component.

condensation(Digraph) -> CondensedDigraph

Types:
- Digraph = CondensedDigraph = digraph()

Creates a digraph where the vertices are the strongly connected components [page 81] of Digraph as returned by strong_components/1. If X and Y are strongly connected components, and there exist vertices x and y in X and Y respectively such that there is an edge emanating [page 81] from x and incident [page 81] on y, then an edge emanating from X and incident on Y is created.
The created digraph has the same type as Digraph. All vertices and edges have the default label [page 81] [].
Each and every cycle [page 81] is included in some strongly connected component, which implies that there always exists a topological ordering [page 81] of the created digraph.

cyclic_strong_components(Digraph) -> [StrongComponent]

Types:
- Digraph = digraph()
- StrongComponent = [vertex()]

Returns a list of strongly connected components [page 81]. Each strongly component is represented by its vertices. The order of the vertices and the order of the components are arbitrary. Only vertices that are included in some cycle [page 81] in Digraph are returned, otherwise the returned list is equal to that returned by strong_components/1.

is_acyclic(Digraph) -> bool()

Types:
- Digraph = digraph()

Returns true if and only if the digraph Digraph is acyclic [page 81].

loop_vertices(Digraph) -> Vertices

Types:
- Digraph = digraph()
- Vertices = [vertex()]

Returns a list of all vertices of Digraph that are included in some loop [page 81].
postorder(Digraph) -> Vertices

Types:
  - Digraph = digraph()
  - Vertices = [vertex()]

Returns all vertices of the digraph Digraph. The order is given by a depth-first traversal
[page 81] of the digraph, collecting visited vertices in postorder. More precisely, the
vertices visited while searching from an arbitrarily chosen vertex are collected in
postorder, and all those collected vertices are placed before the subsequently visited
vertices.

preorder(Digraph) -> Vertices

Types:
  - Digraph = digraph()
  - Vertices = [vertex()]

Returns all vertices of the digraph Digraph. The order is given by a depth-first traversal
[page 81] of the digraph, collecting visited vertices in pre-order.

reachable(Vertices, Digraph) -> Vertices

Types:
  - Digraph = digraph()
  - Vertices = [vertex()]

Returns an unsorted list of digraph vertices such that for each vertex in the list, there is
a path [page 81] in Digraph from some vertex of Vertices to the vertex. In particular,
since paths may have length zero, the vertices of Vertices are included in the returned
list.

reachable_neighbours(Vertices, Digraph) -> Vertices

Types:
  - Digraph = digraph()
  - Vertices = [vertex()]

Returns an unsorted list of digraph vertices such that for each vertex in the list, there is
a path [page 81] in Digraph of length one or more from some vertex of Vertices to
the vertex. As a consequence, only those vertices of Vertices that are included in some
cycle [page 81] are returned.

reaching(Vertices, Digraph) -> Vertices

Types:
  - Digraph = digraph()
  - Vertices = [vertex()]

Returns an unsorted list of digraph vertices such that for each vertex in the list, there is
a path [page 81] from the vertex to some vertex of Vertices. In particular, since paths
may have length zero, the vertices of Vertices are included in the returned list.

reaching_neighbours(Vertices, Digraph) -> Vertices

Types:
digraph(Digraph) = digraph()
Vertices = [vertex()]

Returns an unsorted list of digraph vertices such that for each vertex in the list, there is a path [page 81] of length one or more from the vertex to some vertex of Vertices. As a consequence, only those vertices of Vertices that are included in some cycle [page 81] are returned.

strong_components(Digraph) -> [StrongComponent]

Types:
- Digraph = digraph()
- StrongComponent = [vertex()]

Returns a list of strongly connected components [page 81]. Each strongly component is represented by its vertices. The order of the vertices and the order of the components are arbitrary. Each vertex of the digraph Digraph occurs in exactly one strong component.

subgraph(Digraph, Vertices [, Options]) -> Subgraph | {error, Reason}

Types:
- Digraph = Subgraph = digraph()
- Options = [{type, SubgraphType}, {keep_labels, bool()}]
- Reason = {invalid_option, term()} | {unknown_type, term()}
- SubgraphType = inherit | type()
- Vertices = [vertex()]

Creates a maximal subgraph [page 81] of Digraph having as vertices those vertices of Digraph that are mentioned in Vertices. If the value of the option type is inherit, which is the default, then the type of Digraph is used for the subgraph as well. Otherwise the option value of type is used as argument to digraph:new/1.

If the value of the option keep_labels is true, which is the default, then the labels [page 81] of vertices and edges of Digraph are used for the subgraph as well. If the value is false, then the default label, [], is used for the subgraph’s vertices and edges. subgraph(Digraph, Vertices) is equivalent to subgraph(Digraph, Vertices, []).

topsort(Digraph) -> Vertices | false

Types:
- Digraph = digraph()
- Vertices = [vertex()]

Returns a topological ordering [page 81] of the vertices of the digraph Digraph if such an ordering exists, false otherwise. For each vertex in the returned list, there are no out-neighbours [page 81] that occur earlier in the list.

See Also
digraph [page 74](3)

The Erlang code preprocessor includes functions which are used by `compile` to preprocess macros and include files before the actual parsing takes place.

Exports

- `open(FileName, IncludePath) -> {ok, Epp} | {error, ErrorDescriptor}`
- `open(FileName, IncludePath, PredefMacros) -> {ok, Epp} | {error, ErrorDescriptor}`

Types:
- `FileName = atom() | string()`
- `IncludePath = [DirectoryName]`
- `DirectoryName = atom() | string()`
- `PredefMacros = [{atom(), term()}]`
- `Epp = pid()` - handle to the epp server
- `ErrorDescriptor = term()`

Opens a file for preprocessing.

- `close(Epp) -> ok`

Types:
- `Epp = pid()` - handle to the epp server

Closes the preprocessing of a file.

- `parse_erl_form(Epp) -> {ok, AbsForm} | {eof, Line} | {error, ErrorInfo}`

Types:
- `Epp = pid()`
- `AbsForm = term()`
- `Line = integer()`
- `ErrorInfo = see separate description below.`

Returns the next Erlang form from the opened Erlang source file. The tuple `{eof, Line}` is returned at end-of-file. The first form corresponds to an implicit attribute `-file(File,1)`, where `File` is the name of the file.

- `parse_file(FileName, IncludePath, PredefMacro) -> {ok, [Form]} | {error, OpenError}`

Types:
- `FileName = atom() | string()`
IncludePath = [DirectoryName]
DirectoryName = atom() | string()
PredefMacros = [(atom()),(term())]
Form = term() - same as returned by erl_parse:parse_form

Preprocesses and parses an Erlang source file. Note that the tuple {eof, Line} returned at end-of-file is included as a “form”.

Error Information

The ErrorInfo mentioned above is the standard ErrorInfo structure which is returned from all IO modules. It has the following format:

    {ErrorLine, Module, ErrorDescriptor}

A string which describes the error is obtained with the following call:
apply(Module, format_error, ErrorDescriptor)

See Also

erl_parse [page 95]
erl_eval

Erlang Module

This module provides an interpreter for Erlang expressions. The expressions are in the abstract syntax as returned by erl_parse, the Erlang parser, or a call to io:parse_erl_exprs/2.

Exports

exprs(Expressions, Bindings) -> {value, Value, NewBindings}
exprs(Expressions, Bindings, LocalFunctionHandler) -> {value, Value, NewBindings}

Types:
- Expressions = as returned by erl_parse or io:parse_erl_exprs/2
- Bindings = as returned by bindings/1
- LocalFunctionHandler = {value, Func} | {eval, Func} | none

Evaluates Expressions with the set of bindings Bindings, where Expressions is a sequence of expressions (in abstract syntax) of a type which may be returned by io:parse_erl_exprs/2. See below for an explanation of how and when to use the argument LocalFunctionHandler.

Returns {value, Value, NewBindings}

expr(Expression, Bindings) -> {value, Value, NewBindings}
expr(Expression, Bindings, LocalFunctionHandler) -> {value, Value, NewBindings}

Types:
- Expression = as returned by io:parse_erl_form/2, for example
- Bindings = as returned by bindings/1
- LocalFunctionHandler = {value, Func} | {eval, Func} | none

Evaluates Expression with the set of bindings Bindings. Expression is an expression (in abstract syntax) of a type which may be returned by io:parse_erl_form/2. See below for an explanation of how and when to use the argument LocalFunctionHandler.

Returns {value, Value, NewBindings}

expr_list(ExpressionList, Bindings) -> {ValueList, NewBindings}
expr_list(ExpressionList, Bindings, LocalFunctionHandler) -> {ValueList, NewBindings}
Evaluates a list of expressions in parallel, using the same initial bindings for each expression. Attempts are made to merge the bindings returned from each evaluation. This function is useful in the `LocalFunctionHandler`. See below.

Returns \([\text{ValueList}, \text{NewBindings}]\).

\[\text{new.bindings()} \rightarrow \text{BindingStruct}\]

Returns an empty binding structure.

\[\text{bindings(BindingStruct)} \rightarrow \text{Bindings}\]

Returns the list of bindings contained in the binding structure.

\[\text{binding(Name, BindingStruct)} \rightarrow \text{Binding}\]

Returns the binding of \(\text{Name}\) in \(\text{BindingStruct}\).

\[\text{add.binding(Name, Value, Bindings)} \rightarrow \text{BindingStruct}\]

Adds the binding \(\text{Name} = \text{Value}\) to \(\text{Bindings}\). Returns an updated binding structure.

\[\text{del.binding(Name, Bindings)} \rightarrow \text{BindingStruct}\]

Removes the binding of \(\text{Name}\) in \(\text{Bindings}\). Returns an updated binding structure.

### Local Function Handler

During evaluation of a function, no calls can be made to local functions. An undefined function error would be generated. However, the optional argument `LocalFunctionHandler` may be used to define a function which is called when there is a call to a local function. The argument can have the following formats:

- \{value,Func\} This defines a local function handler which is called with:
  
  \[\text{Func(Name, Arguments)}\]

  \(\text{Name}\) is the name of the local function and \(\text{Arguments}\) is a list of the evaluated arguments. The function handler returns the value of the local function. In this case, it is not possible to access the current bindings. To signal an error, the function handler just calls `exit/1` with a suitable exit value.

- \{eval,Func\} This defines a local function handler which is called with:
  
  \[\text{Func(Name, Arguments, Bindings)}\]

  \(\text{Name}\) is the name of the local function, \(\text{Arguments}\) is a list of the unevaluated arguments, and \(\text{Bindings}\) are the current variable bindings. The function handler returns:

  \{value,Value,NewBindings\}

  \(\text{Value}\) is the value of the local function and \(\text{NewBindings}\) are the updated variable bindings. In this case, the function handler must itself evaluate all the function arguments and manage the bindings. To signal an error, the function handler just calls `exit/1` with a suitable exit value.

- none There is no local function handler.
Bugs

The evaluator is not complete. receive cannot be handled properly.
Any undocumented functions in erl_eval should not be used.
This module performs an identity parse transformation of Erlang code. It is included as an example for users who may wish to write their own parse transformers. If the option \{parse_transform,Module\} is passed to the compiler, a user written function parse_transform/2 is called by the compiler before the code is checked for errors.

Exports

\[
parse_transform(Forms, Options) -> Forms
\]

Types:

- Forms = [erlang_form()]
- Options = [compiler_options()]

Performs an identity transformation on Erlang forms, as an example.

Parse Transformations

Parse transformations are used if a programmer wants to use Erlang syntax, but with different semantics. The original Erlang code is then transformed into other Erlang code.

Note:
Programmers are strongly advised not to engage in parse transformations and no support is offered for problems encountered.

See Also

erl_parse [page 95] compile.
erl_internal

Erlang Module

This module defines Erlang BIFs, guard tests and operators. This module is only of interest to programmers who manipulate Erlang code.

Exports

bif(Name, Arity) -> bool()
Types:
  • Name = atom()
  • Arity = integer()
Returns true if Name/Arity is an Erlang BIF which is automatically recognized by the compiler, otherwise false.

guard_bif(Name, Arity) -> bool()
Types:
  • Name = atom()
  • Arity = integer()
Returns true if Name/Arity is an Erlang BIF which is allowed in guards, otherwise false.

type_test(Name, Arity) -> bool()
Types:
  • Name = atom()
  • Arity = integer()
Returns true if Name/Arity is a valid Erlang type test, otherwise false.

arith_op(OpName, Arity) -> bool()
Types:
  • OpName = atom()
  • Arity = integer()
Returns true if OpName/Arity is an arithmetic operator, otherwise false.

bool_op(OpName, Arity) -> bool()
Types:
  • OpName = atom()
- Arity = integer()
  Returns true if OpName/Arity is a Boolean operator, otherwise false.

    comp_op(OpName, Arity) -> bool()

    Types:
    • OpName = atom()
    • Arity = integer()
    Returns true if OpName/Arity is a comparison operator, otherwise false.

    list_op(OpName, Arity) -> bool()

    Types:
    • OpName = atom()
    • Arity = integer()
    Returns true if OpName/Arity is a list operator, otherwise false.

    send_op(OpName, Arity) -> bool()

    Types:
    • OpName = atom()
    • Arity = integer()
    Returns true if OpName/Arity is a send operator, otherwise false.

    op_type(OpName, Arity) -> Type

    Types:
    • OpName = atom()
    • Arity = integer()
    • Type = arith | bool | comp | list | send
    Returns the Type of operator that OpName/Arity belongs to, or generates a function_clause error if it is not an operator at all.
erl_lint

Erlang Module

This module is used to check Erlang code for illegal syntax and other bugs. It also warns against coding practices which are not recommended.

The errors detected include:

- redefined and undefined functions
- unbound and unsafe variables
- illegal record usage.

Warnings include:

- unused functions and imports
- variables imported into matches
- variables exported from if/case/receive
- variables shadowed in lambdas and list comprehensions.

Some of the warnings are optional, and can be turned on by giving the appropriate option, described below.

The functions in this module are invoked automatically by the Erlang compiler and there is no reason to invoke these functions separately unless you have written your own Erlang compiler.

Exports

module(AbsForms) -> {ok,Warnings} | {error,Errors,Warnings}
module(AbsForms, FileName) -> {ok,Warnings} | {error,Errors,Warnings}
module(AbsForms, FileName, CompileOptions) -> {ok,Warnings} | {error,Errors,Warnings}

Types:

- AbsForms = [term()]
- FileName = FileName2 = atom() | string()
- Warnings = Errors = [{Filename2,[ErrorInfo]}]
- ErrorInfo = see separate description below.
- CompileOptions = [term()]

This function checks all the forms in a module for errors. It returns:

{ok,Warnings} There were no errors in the module.
{error,Errors,Warnings} There were errors in the module.
The elements of `Options` selecting optional warnings are as follows:

{warn_format, Verbose} Causes warnings to be emitted for malformed format strings as arguments to `io:format` and similar functions. `Verbose` selects the amount of warnings: 0 = no warnings; 1 = warnings for invalid format strings and incorrect number of arguments; 2 = warnings also when the validity could not be checked (for example, when the format string argument is a variable). The default verbosity is 1.

warn_unused_vars Causes warnings to be emitted for variables which are not used, with the exception of variables beginning with an underscore ("Prolog style warnings").

The `AbsForms` of a module which comes from a file that is read through `epp`, the Erlang pre-processor, can come from many files. This means that any references to errors must include the file name (see `epp` [page 85], or parser `erl_parse` [page 95]). The warnings and errors returned have the following format:

```erlang
{{FileName2, [ErrorInfo]}}
```

The errors and warnings are listed in the order in which they are encountered in the forms. This means that the errors from one file may be split into different entries in the list of errors.

```erlang
is_guard_test(Expr) -> bool()
```

Types:
- Expr = term()

This function tests if `Expr` is a legal guard test. `Expr` is an Erlang term representing the abstract form for the expression. `erl_parse:parse_exprs(Tokens)` can be used to generate a list of `Expr`.

```erlang
format_error(ErrorDescriptor) -> string()
```

Types:
- ErrorDescriptor = errordesc()

Takes an `ErrorDescriptor` and returns a string which describes the error or warning. This function is usually called implicitly when processing an `ErrorInfo` structure (see below).

### Error Information

The `ErrorInfo` mentioned above is the standard `ErrorInfo` structure which is returned from all IO modules. It has the following format:

```erlang
{ErrorLine, Module, ErrorDescriptor}
```

A string which describes the error is obtained with the following call:

```erlang
apply(Module, format_error, ErrorDescriptor)
```

### See Also

`erl_parse` [page 95], `epp` [page 85]
erl_parse

Erlang Module

This module is the basic Erlang parser which converts tokens into the abstract form of either forms (i.e., top-level constructs), expressions, or terms. Note that a token list must end with the dot token in order to be acceptable to the parse functions (see erl_scan).

Exports

parse_form(Tokens) -> {ok, AbsForm} | {error, ErrorInfo}

Types:
- Tokens = [Token]
- Token = {Tag,Line} | {Tag,Line,term()}
- Tag = atom()
- AbsForm = term()
- ErrorInfo = see section Error Information below.
This function parses Tokens as if it were a form. It returns:

  {ok, AbsForm} The parsing was successful. See section Abstract Form [page 96] below for a description of AbsForm.
  {error, ErrorInfo} An error occurred.

parse_exprs(Tokens) -> {ok, Expr_list} | {error, ErrorInfo}

Types:
- Tokens = [Token]
- Token = {Tag,Line} | {Tag,Line,term()}
- Tag = atom()
- Expr_list = [AbsExpr]
- AbsExpr = term()
- ErrorInfo = see section Error Information below.
This function parses Tokens as if it were a list of expressions. It returns:

  {ok, Expr_list} The parsing was successful. Expr_list is a list of the form AbsExpr, which is described in the section Abstract Form [page 96] below.
  {error, ErrorInfo} An error occurred.

parse_term(Tokens) -> {ok, Term} | {error, ErrorInfo}
Types:

- Tokens = [Token]
- Token = (Tag,Line) | (Tag,Line,term())
- Tag = atom()
- Term = term()
- ErrorInfo = see section Error Information below.

This function parses Tokens as if it were a term. It returns:

{ok, Term} The parsing was successful. Term is the Erlang term corresponding to the token list.
{error, ErrorInfo} An error occurred.

format_error(Descriptor) -> string()
Types:

- ErrorDescriptor = errordesc()

Uses an ErrorDescriptor and returns a string which describes the error. This function is usually called implicitly when an ErrorInfo structure is processed (see below).

tokens(AbsTerm) -> Tokens

tokens(AbsTerm, MoreTokens) -> Tokens
Types:

- Tokens = MoreTokens = [Token]
- Token = (Tag,Line) | (Tag,Line,term())
- Tag = atom()
- AbsTerm = term()
- ErrorInfo = see section Error Information below.

This function generates a list of tokens representing the abstract form AbsTerm of an expression. Optionally, it appends Moretokens.

normalise(AbsTerm) -> Data
Types:

- AbsTerm = Data = term()

Converts the abstract form AbsTerm of a term into a conventional Erlang data structure (i.e., the term itself). This is the inverse of abstract/1.

abstract(Data) -> AbsTerm
Types:

- Data = AbsTerm = term()

Converts the Erlang data structure Data into an abstract form of type AbsTerm. This is the inverse of normalise/1.

Abstract Form

To be supplied
Error Information

The ErrorInfo mentioned above is the standard ErrorInfo structure which is returned from all IO modules. It has the format:

\{ErrorLine, Module, ErrorDescriptor\}

A string which describes the error is obtained with the following call:

apply(Module, format_error, ErrorDescriptor)

See Also

io [page 159], erl_scan [page 101]
The functions in this module are used to generate aesthetically attractive representations of abstract forms, which are suitable for printing. All functions return (possibly deep) lists of characters and generate an error if the form is wrong. All functions can have an optional argument which specifies a hook that is called if an attempt is made to print an unknown form.

Exports

form(Form) -> DeepCharList
form(Form, HookFunction) -> DeepCharList

Types:
- Form = term()
- HookFunction = see separate description below.
- DeepCharList = [char() | DeepCharList]

Pretty prints a Form which is an abstract form of a type which is returned by erl_parse:parse_form.

attribute(Attribute) -> DeepCharList
attribute(Attribute, HookFunction) -> DeepCharList

Types:
- Attribute = term()
- HookFunction = see separate description below.
- DeepCharList = [char() | DeepCharList]

The same as form, but only for the attribute Attribute.

function(Function) -> DeepCharList
function(Function, HookFunction) -> DeepCharList

Types:
- Function = term()
- HookFunction = see separate description below.
- DeepCharList = [char() | DeepCharList]

The same as form, but only for the function Function.
Types:
- Form = term()
- HookFunction = see separate description below.
- DeepCharList = [char()|DeepCharList]

The same as `form`, but only for the guard test `Guard`.

```
exprs(Expressions) -> DeepCharList
.exprs(Expressions, HookFunction) -> DeepCharList
.exprs(Expressions, Indent, HookFunction) -> DeepCharList
```

Types:
- Expressions = term()
- HookFunction = see separate description below.
- Indent = integer()
- DeepCharList = [char()|DeepCharList]

The same as `form`, but only for the sequence of expressions in `Expressions`.

```
expr(Expression) -> DeepCharList
.expr(Expression, HookFunction) -> DeepCharList
.expr(Expression, Indent, HookFunction) -> DeepCharList
.expr(Expression, Indent, Precedence, HookFunction) -> DeepCharList
```

Types:
- Expression = term()
- HookFunction = see separate description below.
- Indent = integer()
- Precedence =
- DeepCharList = [char()|DeepCharList]

This function prints one expression. It is useful for implementing hooks (see below).

### Unknown Expression Hooks

The optional argument `HookFunction`, shown in the functions described above, defines a function which is called when an unknown form occurs where there should be a valid expression. It can have the following formats:

**Function** The hook function is called by:

```
Function(Expr,
    CurrentIndentation,
    CurrentPrecedence,
    HookFunction)
```

**none** There is no hook function

The called hook function should return a (possibly deep) list of characters. `expr/4` is useful in a hook.

If `CurrentIndentation` is negative, there will be no line breaks and only a space is used as a separator.
Bugs

It should be possible to have hook functions for unknown forms at places other than expressions.

See Also

io [page 159], erl_parse [page 95], erl_eval [page 87]
erl_scan

Erlang Module

This module contains functions for tokenizing characters into Erlang tokens

Exports

string(CharList,StartLine) -> {ok, Tokens, EndLine} | Error
string(CharList) -> {ok, Tokens, EndLine} | Error

Types:
- CharList = string()
- StartLine = EndLine = Line = integer()
- Tokens = [{atom(),Line} | {atom(),Line,term()}]
- Error = {error, ErrorInfo, EndLine}

Takes the list of characters CharList and tries to scan (tokenize) them. Returns {ok, Tokens, EndLine}, where Tokens are the Erlang tokens from CharList. EndLine is the last line where a token was found.

StartLine indicates the initial line when scanning starts. string/1 is equivalent to string(CharList,1).

{error, ErrorInfo, EndLine} is returned if an error occurs. EndLine indicates where the error occurred.

tokens(Continuation, CharList, StartLine) -> Return

Types:
- Return = {done, Result, LeftOverChars} | {more, Continuation}
- Continuation = [] | string()
- CharList = string()
- StartLine = EndLine = integer()
- Result = {ok, Tokens, EndLine} | {eof, EndLine}
- Tokens = [{atom(),Line} | {atom(),Line,term()}]

This is the re-entrant scanner which scans characters until a dot (('.' whitespace) has been reached. It returns:

{done, Result, LeftOverChars} This return indicates that there is sufficient input data to get an input. Result is:

{ok, Tokens, EndLine} The scanning was successful. Tokens is the list of tokens including dot.
{eof, EndLine} End of file was encountered before any more tokens.
{error, ErrorInfo, EndLine} An error occurred.
{more, Continuation} More data is required for building a term. Continuation must
be passed in a new call to tokens/3 when more data is available.

reserved_word(Atom) -> bool()
Returns true if Atom is an Erlang reserved word, otherwise false.

format_error(ErrorDescriptor) -> string()
Types:
• ErrorDescriptor = errordesc()
Takes an ErrorDescriptor and returns a string which describes the error or warning.
This function is usually called implicitly when processing an ErrorInfo structure (see
below).

Error Information

The ErrorInfo mentioned above is the standard ErrorInfo structure which is returned
from all IO modules. It has the following format:

{ErrorLine, Module, ErrorDescriptor}
A string which describes the error is obtained with the following call:
apply(Module, format_error, ErrorDescriptor)

Notes

The continuation of the first call to the re-entrant input functions must be []. Refer to
Armstrong, Virding and Williams, "Concurrent Programming in Erlang", Chapter 13, for
a complete description of how the re-entrant input scheme works.

io [page 159] erl_parse [page 95]
This module is an interface to the Erlang built-in term storage BIFs. These provide the ability to store very large quantities of data in an Erlang runtime system, and to have constant access time to the data. (In the case of ordered_set, see below, access time is proportional to the logarithm of the number of objects stored).

Data is organized as a set of dynamic tables, which can store tuples. Each table is created by a process. When the process terminates, the table is automatically destroyed. Every table has access rights set at creation.

Tables are divided into four different types, set, ordered_set, bag and duplicate_bag. A set or ordered_set table can only have one object associated with each key. A bag or duplicate_bag can have many objects associated with each key.

The number of tables stored at one Erlang node is limited. The current default limit is approximately 1400 tables. The upper limit can be increased by setting the environment variable ERL_MAX_ETS_TABLES before starting the Erlang runtime system (i.e. with the -env option to erl/werl). The actual limit may be slightly higher than the one specified, but never lower.

Note that there is no automatic garbage collection for tables. Even if there are no references to a table from any process, it will not automatically be destroyed unless the owner process terminates. It can be destroyed explicitly by using delete/1.

Some implementation details:

- In the current implementation, every object insert and look-up operation results in one copy of the object.
- This module provides very limited support for concurrent updates. No locking is available, but the safe_fixtable/2 function can be used to guarantee that a sequence of first/1 and next/2 calls will traverse the table without errors even if another process (or the same process) simultaneously deletes or inserts objects in the table.
- `$end_of_table` should not be used as a key since this atom is used to mark the end of the table when using first/next.

In general, the functions below will exit with reason badarg if any argument is of the wrong format, or if the table identifier is invalid.

The type tid() is used to denote a table identifier. Note that the internal structure of this type is implementation-specific.
Exports

all() -> [Tab]

Types:
- Tab = tid() | atom()

Returns a list of all tables at the node. Named tables are given by their names, unnamed tables are given by their table identifiers.

delete(Tab) -> true

Types:
- Tab = tid() | atom()

Deletes the entire table Tab.

delete(Tab, Key) -> true

Types:
- Tab = tid() | atom()
- Key = term()

Deletes all objects with the key Key from the table Tab.

delete_all_objects(Tab) -> true

Types:
- Tab = tid() | atom()

Delete all objects in the ETS table Tab. The deletion is atomic.

delete_object(Tab, Object) -> true

Types:
- Tab = tid() | atom()
- Object = tuple()

Delete the exact object Object from the ETS table, leaving objects with the same key but other differences (useful for type bag).

file2tab(Filename) -> {ok, Tab} | {error, Reason}

Types:
- Filename = string() | atom()
- Tab = tid() | atom()
- Reason = term()

Reads a file produced by tab2file/2 and creates the corresponding table Tab.

first(Tab) -> Key | '$end_of_table'

Types:
- Tab = tid() | atom()
- Key = term()
Returns the first key Key in the table Tab. If the table is of the ordered_set type, the first key in Erlang term order will be returned. If the table is of any other type, the first key according to the table's internal order will be returned. If the table is empty, '$end_of_table' will be returned.
Use next/2 to find subsequent keys in the table.

```
fixtable(Tab, true|false) -> true | false
```

Types:
- Tab = tid() | atom()

**Warning:**
The function is retained for backwards compatibility only. Use safe_fixtable/2 instead.

Fixes a table for safe traversal. The function is primarily used by the Mnesia DBMS to implement functions which allow write operations in a table, although the table is in the process of being copied to disk or to another node. It does not keep track of when and how tables are fixed.

```
foldl(Function, Acc0, Tab) -> Acc1
```

Types:
- Function = fun(A, AccIn) -> AccOut
- Tab = tid() | atom()
- Acc0 = Acc1 = AccIn = AccOut = term()

Acc0 is returned if the table is empty. This function is similar to lists:foldl/3. The order in which the elements of the table are traversed is unspecified, except for tables of type ordered_set, for which they are traversed first to last. Since safe_fixtable/2 is called, the table must be public or owned by the calling process.

```
foldr(Function, Acc0, Tab) -> Acc1
```

Types:
- Function = fun(A, AccIn) -> AccOut
- Tab = tid() | atom()
- Acc0 = Acc1 = AccIn = AccOut = term()

Acc0 is returned if the table is empty. This function is similar to lists:foldr/3. The order in which the elements of the table are traversed is unspecified, except for tables of type ordered_set, for which they are traversed last to first. Since safe_fixtable/2 is called, the table must be public or owned by the calling process.

```
from_dets(Tab, DetsTab) -> Tab
```

Types:
- Tab = tid() | atom()
- DetsTab = atom()
Fills an already created ETS table with the objects in the already opened DETS table named \texttt{DetsTab}. The ETS table is emptied before the objects are inserted.

\[
i() \rightarrow \text{void()}
\]

Displays information about all ETS tables on tty.

\[
i(Tab) \rightarrow \text{void()}
\]

Types:
- \texttt{Tab = tid() \mid atom()}

Browses the table \texttt{Tab} on tty.

\[
\text{info(Tab)} \rightarrow \{\{\text{Item,Value}\}\mid \text{undefined}\}
\]

Types:
- \texttt{Tab = tid() \mid atom()}
- \texttt{Item, Value - see below}

Returns information about the table \texttt{Tab} as a list of \{\text{Item,Value}\} tuples:

- \texttt{Item=memory, Value=int()}
  The number of words allocated to the table.
- \texttt{Item=owner, Value=pid()}
  The pid of the owner of the table.
- \texttt{Item=name, Value=atom()}
  The name of the table.
- \texttt{Item=size, Value=int()}
  The number of objects inserted in the table.
- \texttt{Item=node, Value=atom()}
  The node where the table is stored. This field is no longer meaningful as tables cannot be accessed from other nodes.
- \texttt{Item=named_table, Value=true|false}
  Indicates if the table is named or not.
- \texttt{Item=type, Value=set|ordered_set|bag|duplicate_bag}
  The table type.
- \texttt{Item=keypos, Value=int()}
  The key position.
- \texttt{Item=protection, Value=public|protected|private}
  The table access rights.

\[
\text{info(Tab, Item)} \rightarrow \text{Value \mid undefined}
\]

Types:
- \texttt{Tab = tid() \mid atom()}
- \texttt{Item, Value - see below}

Returns the information associated with \texttt{Item} for the table \texttt{Tab}. In addition to the \{\text{Item,Value}\} pairs defined for \text{info/1}, the following items are allowed:
- Item=fixed, Value=true|false
  Indicates if the table is fixed by any process or not.
- Item=safe_fixed, Value={FirstFixed, Info}|false
  If the table has been fixed using safe_fixmap/2, the call returns a tuple where
  FirstFixed is the time when the table was first fixed by a process, which may or
  may not be one of the processes it is fixed by right now.
  Info is a possibly empty lists of tuples [Pid, RefCount], one tuple for every
  process the table is fixed by right now. RefCount is the value of the reference
  counter, keeping track of how many times the table has been fixed by the process.
  If the table never has been fixed, the call returns false.

\texttt{init_table(Name, InitFun) \to \text{true}}

\text{Types:}
- Name = atom()
- InitFun = fun(Arg) \to Res
- Arg = read | close
- Res = end_of_input | {[object()], InitFun} | term()

Replaces the existing objects of the table \texttt{Tab} with objects created by calling the input
function \texttt{InitFun}, see below. This function is provided for compatibility with the
DETS module, it's not more efficient than filling a table by using \texttt{ets:insert/2}.

When called with the argument \texttt{read} the function \texttt{InitFun} is assumed to return
\texttt{end_of_input} when there is no more input, or \{Objects, Fun\}, where \texttt{Objects} is a list
of objects and \texttt{Fun} is a new input function. Any other value \texttt{Value} is returned as an error
\{error, \{init_fun, Value\}\}. Each input function will be called exactly once, and
should an error occur, the last function is called with the argument \texttt{close}, the reply of
which is ignored.

If the type of the table is \texttt{set} and there is more than one object with a given key, one of
the objects is chosen. This is not necessarily the last object with the given key in the
sequence of objects returned by the input functions. This holds also for duplicated
objects stored in tables of type \texttt{duplicate_bag}.

\texttt{insert(Tab, ObjectOrObjects) \to \text{true}}

\text{Types:}
- Tab = tid() | atom()
- ObjectOrObjects = tuple() | [tuple()]

Inserts the object or all of the objects in the list \texttt{ObjectOrObjects} into the table \texttt{Tab}. If
there already exists an object with the same key as one of the objects, and the table is a
\texttt{set} or \texttt{ordered_set} table, the old object will be replaced. If the list contains more than
one object with the same key and the table is a \texttt{set/ordered_set}, one will be inserted,
which one is not defined.

\texttt{last(Tab) \to Key | '$end_of_table'}

\text{Types:}
- Tab = tid() | atom()
- Key = term()
Returns the last key \texttt{Key} according to Erlang term order in the table \texttt{Tab} of the \texttt{ordered_set} type. If the table is of any other type, the function is synonymous to \texttt{first/2}. If the table is empty, \texttt{'$end_of_table'} is returned.

Use \texttt{prev/2} to find preceding keys in the table.

\begin{verbatim}
lookup(Tab, Key) -> [Object]

Types:
- \texttt{Tab} = tid() \mid atom()
- \texttt{Key} = term()
- \texttt{Object} = tuple()

Returns a list of all objects with the key \texttt{Key} in the table \texttt{Tab}.

If the table is of type \texttt{set} or \texttt{ordered_set}, the function returns either the empty list or a list with one element, as there cannot be more than one object with the same key. If the table is of type \texttt{bag} or \texttt{duplicate_bag}, the function returns a list of arbitrary length.

Note that the time order of object insertions is preserved; The first object inserted with the given key will be first in the resulting list, and so on.

Insert and look-up times in tables of type \texttt{set}, \texttt{bag} and \texttt{duplicate_bag} are constant, regardless of the size of the table. For the \texttt{ordered_set} data-type, time is proportional to the (binary) logarithm of the number of objects.

\begin{verbatim}
lookup_element(Tab, Key, Pos) -> Elem

Types:
- \texttt{Tab} = tid() \mid atom()
- \texttt{Key} = term()
- \texttt{Pos} = int()
- \texttt{Elem} = term() \mid [term()]

If the table \texttt{Tab} is of type \texttt{set} or \texttt{ordered_set}, the function returns the \texttt{Pos}:th element of the object with the key \texttt{Key}.

If the table is of type \texttt{bag} or \texttt{duplicate_bag}, the functions returns a list with the \texttt{Pos}:th element of every object with the key \texttt{Key}.

If no object with the key \texttt{Key} exists, the function will exit with reason \texttt{badarg}.

\begin{verbatim}
match(Tab, Pattern) -> [Match]

Types:
- \texttt{Tab} = tid() \mid atom()
- \texttt{Pattern} = tuple()
- \texttt{Match} = [term()]

Matches the objects in the table \texttt{Tab} against the pattern \texttt{Pattern}.

A pattern is a term that may contain:

- bound parts (Erlang terms),
- \'\_\' which matches any Erlang term, and
- pattern variables: \texttt{'$N'} where \texttt{N}=0,1,...
\end{verbatim}
The function returns a list with one element for each matching object, where each element is an ordered list of pattern variable bindings. An example:

```plaintext
> ets:match(T, '$1'). % Matches every object in the table
[[rufsen,dog,7],[brunte,horse,5],[ludde,dog,5]]
> ets:match(T, {'_',dog,'$1'}). [[7],[5]]
> ets:match(T, {'_',cow,'$1'}). []
```

If the key is specified in the pattern, the match is very efficient. If the key is not specified, i.e. if it is a variable or an underscore, the entire table must be searched. The search time can be substantial if the table is very large.

On tables of the ordered_set type, the result is in the same order as in a first/next traversal.

`match(Tab, Pattern, Limit) -> [{[Match],Continuation} | '$end_of_table']`

Types:
- `Tab = tid() | atom()`
- `Pattern = tuple()`
- `Match = [term()]`
- `Continuation = term()`

Works like `ets:match/2` but only returns a limited (Limit) number of matching objects. The Continuation term can then be used in subsequent calls to `ets:match/1` to get the next chunk of matching objects. This is a space efficient way to work on objects in a table which is still faster than traversing the table object by object using `ets:first/1` and `ets:next/1`.

'$end_of_table' is returned if the table is empty.

`match(Continuation) -> [{[Match],Continuation} | '$end_of_table']`

Types:
- `Match = [term()]`
- `Continuation = term()`

Continues a match started with `ets:match/3`. The next chunk of the size given in the initial `ets:match/3` call is returned together with a new Continuation that can be used in subsequent calls to this function.

'$end_of_table' is returned when there are no more objects in the table.

`match_delete(Tab, Pattern) -> true`

Types:
- `Tab = tid() | atom()`
- `Pattern = tuple()`

Deletes all objects which match the pattern `Pattern` from the table `Tab`. See `match/2` for a description of patterns.

`match_object(Tab, Pattern) -> [Object]`
Types:
- Tab = tid() \| atom()
- Pattern = tuple()
- Match = [term()]
- Continuation = term()

**match_object(Tab, Pattern, Limit)** -> \{[Match], Continuation\} | '$end_of_table'

Types:
- Tab = tid() \| atom()
- Pattern = tuple()
- Match = [term()]
- Continuation = term()

Works like ets:match_object/2 but only returns a limited (Limit) number of matching objects. The Continuation term can then be used in subsequent calls to ets:match_object/1 to get the next chunk of matching objects. This is a space efficient way to work on objects in a table which is still faster than traversing the table object by object using ets:first/1 and ets:next/1.

'end_of_table' is returned if the table is empty.

**match_object(Continuation)** -> \{[Match], Continuation\} | '$end_of_table'

Types:
- Match = [term()]
- Continuation = term()

Continues a match started with ets:match_object/3. The next chunk of the size given in the initial ets:match_object/3 call is returned together with a new Continuation that can be used in subsequent calls to this function.

'end_of_table' is returned when there are no more objects in the table.

**member(Tab, Key)** -> true \| false

Types:
- Tab = tid() \| atom()
- Key = term()

Works like lookup/2, but does not return the objects. The function returns true if one or more elements in the table has the key Key, false otherwise.

**new(Name, Options)** -> tid()

Types:
- Name = atom()
- Options = [Option]
Option = Type \| Access \| \text{named_table} \| \{keypos, Pos\}

Type = set \| \text{ordered_set} \| \text{bag} \| \text{duplicate_bag}

Access = public \| protected \| private

Pos = int()

Creates a new table and returns a table identifier which can be used in subsequent operations. The table identifier can be sent to other processes so that a table can be shared between different processes within a node.

The parameter \text{Options} is a list of atoms which specifies table type, access rights, key position and if the table is named or not. If one or more options are left out, the default values are used. This means that not specifying any options (\[\]) is the same as specifying [set, protected, \{keypos, 1\}].

\begin{itemize}
  \item \text{set} The table is a \text{set} table - one key, one object, no order among objects. This is the default table type.
  \item \text{ordered_set} The table is a \text{ordered_set} table - one key, one object, ordered in Erlang term order, which is the order implied by the < and > operators. Tables of this type have a somewhat different behavior in some situations than tables of the other types.
  \item \text{bag} The table is a \text{bag} table which can have many objects, but only one instance of each object, per key.
  \item \text{duplicate_bag} The table is a \text{duplicate_bag} table which can have many objects, including multiple copies of the same object, per key.
  \item \text{public} Any process may read or write to the table.
  \item \text{protected} The owner process can read and write to the table. Other processes can only read the table. This is the default setting for the access rights.
  \item \text{private} Only the owner process can read or write to the table.
  \item \text{named_table} If this option is present, the name \text{Name} is associated with the table identifier. The name can then be used instead of the table identifier in subsequent operations.
  \item \{keypos, Pos\} Specifies which element in the stored tuples should be used as key. By default, it is the first element, i.e. \text{Pos}=1. However, this is not always appropriate. In particular, we do not want the first element to be the key if we want to store Erlang records in a table.
\end{itemize}

Note that any tuple stored in the table must have at least \text{Pos} number of elements.

\begin{verbatim}
next(Tab, Key1) -> Key2 | '$end_of_table'

Types:
  \text{Tab} = \text{tid()} \| \text{atom()}
  \text{Key1} = \text{Key2} = \text{term()}
\end{verbatim}

Returns the next key \text{Key2}, following the key \text{Key1} in the table \text{Tab}. If the table is of the \text{ordered_set} type, the next key in Erlang term order is returned. If the table is of any other type, the next key according to the table's internal order is returned. If there is no next key, '$end_of_table' is returned.

Use first/1 to find the first key in the table.

Unless a table of type set, bag or duplicate_bag is protected using safe_fixtable/2, see below, a traversal may fail if concurrent updates are made to the table. If the table is
of type `ordered_set`, the function returns the next key in order, even if the object does no longer exist.

\[
\text{prev}(\text{Tab}, \text{Key1}) \rightarrow \text{Key2} \mid \text{'$end_of_table'}
\]

Types:
- \(\text{Tab} = \text{tid()} \mid \text{atom()}\)
- \(\text{Key1} = \text{Key2} = \text{term()}\)

Returns the previous key \(\text{Key2}\), preceding the key \(\text{Key1}\) according the Erlang term order in the table \(\text{Tab}\) of the `ordered_set` type. If the table is of any other type, the function is synonymous to `next/2`. If there is no previous key, \text{'end_of_table'} is returned.

Use `last/1` to find the last key in the table.

\[
\text{rename}(\text{Tab}, \text{Name}) \rightarrow \text{Name}
\]

Types:
- \(\text{Tab} = \text{Name} = \text{atom}()\)

Renames the named table \(\text{Tab}\) to the new name \(\text{Name}\). Afterwards, the old name can not be used to access the table. Renaming an unnamed table has no effect.

\[
\text{safe_fixtable}(\text{Tab}, \text{true}|\text{false}) \rightarrow \text{true} \mid \text{false}
\]

Types:
- \(\text{Tab} = \text{tid()} \mid \text{atom}()\)

Fixes a table of the `set`, `bag` or `duplicate_bag` table type for safe traversal.

A process fixes a table by calling `safe_fixtable(\text{Tab},\text{true})`. The table remains fixed until the process releases it by calling `safe_fixtable(\text{Tab},\text{false})`, or until the process terminates.

If several processes fix a table, the table will remain fixed until all processes have released it (or terminated). A reference counter is kept on a per process basis, and \(N\) consecutive fixes requires \(N\) releases to actually release the table.

When a table is fixed, a sequence of `first/1` and `next/2` calls are guaranteed to succeed even if objects are removed during the traversal. An example:

\[
\text{clean_all_with_value}(\text{Tab},X) \rightarrow
\text{safe_fixtable}(\text{Tab},\text{true}),
\text{clean_all_with_value}(\text{Tab},X,\text{ets:first}(\text{Tab})),
\text{safe_fixtable}(\text{Tab},\text{false}).
\]

\[
\text{clean_all_with_value}(\text{Tab},X,\text{'$end_of_table'}) \rightarrow
\text{true};
\text{clean_all_with_value}(\text{Tab},X,\text{Key}) \rightarrow
\text{case ets:lookup}(\text{Tab},\text{Key}) of
\quad [[\text{Key},\text{X}]] \rightarrow
\quad \text{ets:delete}(\text{Tab},\text{Key});
\quad \rightarrow
\quad \text{true}
\end{case}
\]

end,
\text{clean_all_with_value}(\text{Tab},X,\text{ets:next}(\text{Tab},\text{Key})).
Note that no deleted objects are actually removed from a fixed table until it has been released. If a process fixes a table but never releases it, the memory used by the deleted objects will never be freed. The performance of operations on the table will also degrade significantly.

Use info/2 to retrieve information about which processes have fixed which tables. A system with a lot of processes fixing tables may need a monitor which sends alarms when tables have been fixed for too long.

Note that for tables of the ordered set type, safe_fixmap/2 is not necessary as calls to first/1 and next/2 will always succeed.

select(Tab, MatchSpec) -> [Object]

Types:
- Tab = tid() | atom()
- Object = tuple()
- MatchSpec = term()

Matches the objects in the table Tab using a match_spec as described in ERTS users guide. This is a more general call than the ets:match/2 and ets:match_object/2 calls. In its simplest forms the match_spec's look like this:

- MatchSpec = [MatchFunction]
- MatchFunction = {MatchHead, [Guard], [Result]}
- MatchHead = “Pattern as in ets:match”
- Guard = {“Guardtest name”, ...}
- Result = “Term construct”

This means that the match_spec is always a list of one or more tuples (of arity 3). The tuples first element should be a pattern as described in the documentation of ets:match/2. The second element of the tuple should be a list of 0 or more guard tests (described below). The third element of the tuple should be a list containing a description of the value to actually return. In almost all normal cases the list contains exactly one term which fully describes the value to return for each object.

The return value is constructed using the “match variables” bound in the MatchHead or using the special match variables ‘$’ (the whole matching object) and ‘$$’ (all match variables in a list), so that the following <c>ets:match/2 expression:

    ets:match(Tab,{'$1','$2','$3'})

is exactly equivalent to:

    ets:select(Tab,[[{'$1','$2','$3'},[],['$$']]])

- and the following ets:match_object/2 call:

    ets:match_object(Tab,{'$1','$2','$1'})

is exactly equivalent to

    ets:select(Tab,[[{'$1','$2','$1'},[],['$_']]])

Composite terms can be constructed in the Result part either by simply writing a list, so that this code:

    ets:select(Tab,[[{'$1','$2','$3'},[],['$$']]])
gives the same output as:

```erlang
ets:select(Tab, [{('$1', '$2', '$3'), [], [], ['$_']})])
```

i.e. all the bound variables in the match head as a list. If tuples are to be constructed, one has to write a tuple of arity 1 with the single element in the tuple being the tuple one wants to construct (as an ordinary tuple could be mistaken for a guard). Therefore the following call:

```erlang
ets:select(Tab, [{('$1', '$2', '$1'), [], [], ['$_']})])
```

gives the same output as:

```erlang
ets:select(Tab, [{('$1', '$2', '$1'), [], [], ['$_']})])
```

- this syntax is equivalent to the syntax used in the trace patterns (see the `dbg` module in the `runtime_tools` application).

The Guard’s are constructed as tuples where the first element is the name of the test (again, see the `match_spec` documentation in ERTS users guide) and the rest of the elements are the parameters of the test. To check for a specific type (say a list) of the element bound to the match variable '$_', one would write the test as `{is_list, '$_'}`. If the test fails, the object in the table won’t match and the next MatchFunction (if any) will be tried. Most guard tests present in erlang can be used, but only the new versions prefixed `is_` are allowed (like `is_float`, `is_atom` etc). An exact list of the allowed guard tests is present in the `match_spec` section of ERTS users guide.

The Guard section can also contain logic and arithmetic operations, which are written with the same syntax as the guard tests (prefix notation), so that a guard test written in erlang looking like this:

```erlang
is_integer(X), is_integer(Y), X + Y < 4711
```

is expressed like this (X replaced with '$_' and Y with '$2'):

```
[{is_integer, '$_'}, {is_integer, '$2'}, {'<', {'+', '$_', '$2'}, 4711}]
```

A complete list of the operators is present in the `match_spec` section of ERTS users guide.

```erlang
select(Tab, MatchSpec, Limit) -> {[Match], Continuation} | '$end_of_table'
```

Types:

- Tab = tid() | atom()
- Object = tuple()
- MatchSpec = term()
- Continuation = term()

Works like `ets:select/2` but only returns a limited (Limit) number of matching objects. The Continuation term can then be used in subsequent calls to `ets:select/1` to get the next chunk of matching objects. This is a space efficient way to work on objects in a table which is still faster than traversing the table object by object using `ets:first/1` and `ets:next/1`.

‘$end_of_table’ is returned if the table is empty.

```erlang
select(Continuation) -> {[Match], Continuation} | '$end_of_table'
```

Types:
Match = [term()]
Continuation = term()

Continues a match started with ets:select/3. The next chunk of the size given in the initial ets:select/3 call is returned together with a new Continuation that can be used in subsequent calls to this function.

'$end_of_table' is returned when there are no more objects in the table.

slot(Tab, I) -> [Object] | '$end_of_table'

Types:
- Tab = tid() | atom()
- I = int()
- Object = tuple()

**Warning:**
The function is deprecated and may be removed from future releases. Use first/next or last/prev instead.

Returns all objects in the I:th slot of the table Tab. A table can be traversed by repeatedly calling the function, starting with the first slot I=0 and ending when '$end_of_table' is returned. The function will fail with reason badarg if the I argument is out of range.

Unless a table of type set, bag or duplicate_bag is protected using safe_fixtable/2, see above, a traversal may fail if concurrent updates are made to the table. If the table is of type ordered_set, the function returns a list containing the I:th object in Erlang term order.

tab2file(Tab, Filename) -> ok | {error,Reason}

Types:
- Tab = tid() | atom()
- Filename = string() | atom()
- Reason = term()

Dumps the table Tab to the file Filename. The implementation of this function is not efficient.

tab2list(Tab) -> [Object]

Types:
- Tab = tid() | atom()
- Object = tuple()

Returns a list of all objects in the table Tab.

test_ms(Tuple, MatchSpec) -> {ok, Result} | {error, Errors}

Types:
- Tuple = tuple()
This function is a utility to test the match spec's used in calls to `ets:select/2`. The function both tests the match spec for "syntactic" correctness and runs the match spec against the object `Tuple`. If the match spec contains errors, the tuple `{error, Errors}` is returned where `Errors` is a list of natural language descriptions of what was wrong with the match spec. If the match spec is syntactically OK, the function returns `{ok,Term}` where `Term` is what would have been the result in a real `ets:select/2` call or `false` if the match spec does not match the object `Tuple`.

This is a useful debugging and test tool, especially when writing complicated `ets:select/2` calls.

```
to_dets(Tab, DetsTab) -> Tab
  Types:
  • Tab = tid() | atom()
  • DetsTab = atom()
  Fills an already created/opened DETS table with the objects in the already opened ETS table named `Tab`. The DETS table is emptied before the objects are inserted.
```

```
update_counter(Tab, Key, {Pos,Incr}) -> Result
update_counter(Tab, Key, Incr) -> Result
  Types:
  • Tab = tid() | atom()
  • Key = term()
  • Pos = Incr = Result = int()
  This function provides an efficient way to update a counter, without the hassle of having to look up an object, update the object by incrementing an element and insert the resulting object into the table again.
  It will destructively update the object with key `Key` in the table `Tab` by adding `Incr` to the element at the `Pos`:th position. The new counter value is returned. If no position is specified, the element directly following the key (\(<\text{keypos}>+1\)) is updated.
  The function will fail with reason `badarg` if:
  • the table is not of type `set` or `ordered_set`,
  • no object with the right key exists,
  • the object has the wrong arity, or,
  • the element to update is not an integer.
```
file_sorter

Erlang Module

The functions of this module sort terms on files, merge already sorted files, and check files for sortedness. Chunks containing binary terms are read from a sequence of files, sorted internally in memory and written on temporary files, which are merged producing one sorted file as output. Merging is provided as an optimization; it is faster when the files are already sorted, but it always works to sort instead of merge.

On a file, a term is represented by a header and a binary. Two options define the format of terms on files:

- \{header, HeaderLength\}. HeaderLength determines the number of bytes preceding each binary and containing the length of the binary in bytes. Default is 4. The order of the header bytes is defined as follows: if \(B\) is a binary containing a header only, the size \(\text{Size}\) of the binary is calculated as \(<<\text{Size}:\text{HeaderLength}/\text{unit}:8>> = B\).

- \{format, Format\}. The format determines the function that is applied to binaries in order to create the terms that will be sorted. The default value is \text{binary_term}, which is equivalent to \text{fun binary_to_term/1}. If \text{Format is term}, \text{io:read/2} is called to read terms. In that case only the default value of the header option is allowed. The format option also determines what is written to the sorted output file: if \text{Format is term} then \text{io:format/3} is called to write each term, otherwise the binary prefixed by a header is written. Note that the binary written is the same binary that was read; the results of applying the \text{Format} function are thrown away as soon as the terms have been sorted. Reading and writing terms using the \text{io} module is very much slower than reading and writing binaries.

Other options are:

- \{order, Order\}. The default is to sort terms in ascending order, but that can be changed by the value \text{descending} or by giving an ordering function \text{Fun}. \text{Fun}(A, B) should return \text{true} if \(A\) comes before \(B\) in the ordering, \text{false} otherwise. The \text{keysort}, \text{keymerge} and \text{keycheck} functions do not accept ordering functions. Using an ordering function will slow down the sort considerably.

- \{unique, \text{bool()}\}. When sorting or merging files, only the first of a sequence of terms that compare equal is output if this option is set to \text{true}. The default value is \text{false} which implies that all terms that compare equal are output. When checking files for sortedness, a check that no pair of consecutive terms compares equal is done if this option is set to \text{true}.

- \{tmpdir, TempDirectory\}. The directory where temporary files are put can be chosen explicitly. The default, implied by the value ",", is to put temporary files on the same directory as the sorted output file. If output is a function (see below), the directory returned by \text{file:get_cwd()} is used instead. The names of temporary files are derived from the pid doing the sort; a typical name would be \text{file_sorter_0.28.0.17}, where \(17\) is a sequence number. Existing files will be overwritten. Temporary files are deleted unless some uncaught \text{EXIT} signal occurs.

STDLIB 117
- \{\text{compressed}, \text{bool}\}\}. Temporary files and the output file may be compressed. The default value \text{false} implies that written files are not compressed. Regardless of the value of the \text{compressed} option, compressed files can always be read. Note that reading and writing compressed files is significantly slower than reading and writing uncompressed files.

- \{\text{size}, \text{Size}\}. By default approximately 512 kilobytes read from files are sorted internally. There is seldom any need to change this.

- \{\text{no files}, \text{NoFiles}\}. By default 16 files are merged at a time. There is seldom any need to change this.

To summarize, here is the syntax of the options:

- \text{Options = [Option] | Option}
- \text{Option = \{\text{header, HeaderLength} | \{\text{format, Format} | \{\text{order, Order} | \{\text{unique, bool()} | \{\text{tmpdir, TempDirectory} | \{\text{compressed, bool()}\}
- \text{HeaderLength = int()} \geq 0
- \text{Format = binary_term | term | FormatFun}
- \text{FormatFun = fun(Binary) \rightarrow Term}
- \text{Order = ascending | descending | OrderFun}
- \text{OrderFun = fun(Term, Term) \rightarrow bool()}
- \text{TempDirectory = "" | file\_name()}
- \text{Size = int()} \geq 0
- \text{NoFiles = int()} \geq 1

As an alternative to sorting files, a function of one argument can be given as input. When called with the argument \text{read} the function is assumed to return \text{end of input} when there is no more input, or \{\text{Objects, Fun}\}, where \text{Objects} is a list of binaries or terms depending on the format and \text{Fun} is a new input function. Any other value is immediately returned as value of the current call to \text{sort} or \text{keysort}. Each input function will be called exactly once, and should an error occur, the last function is called with the argument \text{close}, the reply of which is ignored.

A function of one argument can be given as output. The results of sorting or merging the input is collected in a non-empty sequence of variable length lists of binaries or terms depending on the format. The output function is called with one list at a time, and is assumed to return a new output function. Any other return value is immediately returned as value of the current call to the \text{sort} or \text{merge} function. Each output function is called exactly once. When some output function has been applied to all of the results or an error occurs, the last function is called with the argument \text{close}, and the reply is returned as value of the current call to the \text{sort} or \text{merge} function.

As an example, consider sorting the terms on a disk log file. A function that reads chunks from the disk log and returns a list of binaries is used as input. The results are collected in a list of terms.

```
sort(Log) \rightarrow
  \{\text{ok, _} = \text{disk\_log:open([\{\text{name, Log}, \{\text{mode, read\_only}\}\])},\}
  \text{Input = input(Log, start)},\n  \text{Output = output([])},\n  \text{Reply = file\_sorter:sort(Input, Output, \{\text{format, term}\})},\n  \text{ok = disk\_log:close(Log)},\n```

As an example, consider sorting the terms on a disk log file. A function that reads chunks from the disk log and returns a list of binaries is used as input. The results are collected in a list of terms.
Reply.

input(Log, Cont) ->
  fun(close) ->
    ok;
  (read) ->
    case disk_log:chunk(Log, Cont) of
      {error, Reason} ->
        {error, Reason};
      {Cont2, Terms} ->
        {Terms, input(Log, Cont2)};
      {Cont2, Terms, _Badbytes} ->
        {Terms, input(Log, Cont2)};
      eof ->
        end_of_input
    end
  end.
end.

output(L) ->
  fun(close) ->
    lists:append(lists:reverse(L));
  (Terms) ->
    output([Terms | L])
  end.
end.

Further examples of functions as input and output can be found at the end of the file_sorter module; the term format is implemented with functions.

The possible values of Reason returned when an error occurs are:

- `bad_object`, `{bad_object, FileName}`. Applying the format function failed for some binary, or the key(s) could not be extracted from some term.

- `bad_term`, `{bad_term, FileName}`. `io:read/2` failed to read some term.

- `{file_error, FileName, Reason2}`. See the file module for an explanation of Reason2.

- `{premature_eof, FileName}`. End-of-file was encountered inside some binary term.

- `{not_a_directory, FileName}`. The file supplied with the `tmpdir` option is not a directory.

Types

```
Binary = binary()
FileName = filename()
FileNames = [FileName]
ICommand = read | close
IReply = end_of_input | {[Object], Infun} | InputReply
Infun = fun(ICommand) -> IReply
Input = FileNames | Infun
InputReply = Term
KeyPos = int() > 0 | [int() > 0]
OCommand = [Object] | close
OReply = Outfun | OutputReply
Object = Term | Binary
```
Outfun = fun(OCommand) -> OReply
Output = FileName | Outfun
OutputReply = Term
Term = term()

Exports

sort(FileName) -> Reply
sort(Input, Output) -> Reply
sort(Input, Output, Options) -> Reply

Types:
- Reply = ok | {error, Reason} | InputReply | OutputReply
Sorts terms on files
sort(FileName) is equivalent to sort([FileName], FileName).
sort(Input, Output) is equivalent to sort(Input, Output, []).

keysort(KeyPos, FileName) -> Reply
keysort(KeyPos, Input, Output) -> Reply
keysort(KeyPos, Input, Output, Options) -> Reply

Types:
- Reply = ok | {error, Reason} | InputReply | OutputReply
Sorts tuples on files. The sort is performed on the element(s) mentioned in KeyPos. If two tuples compare equal on one element, next element according to KeyPos is compared. The sort is stable.
keysort(N, FileName) is equivalent to keysort(N, [FileName], FileName).
keysort(N, Input, Output) is equivalent to keysort(N, Input, Output, []).

merge(FileNames, Output) -> Reply
merge(FileNames, Output, Options) -> Reply

Types:
- Reply = ok | {error, Reason} | OutputReply
Merges terms on files. Each input file is assumed to be sorted.
merge(FileNames, Output) is equivalent to merge(FileNames, Output, []).

keymerge(KeyPos, FileNames, Output) -> Reply
keymerge(KeyPos, FileNames, Output, Options) -> Reply

Types:
- Reply = ok | {error, Reason} | OutputReply
Merges tuples on files. Each input file is assumed to be sorted.
keymerge(KeyPos, FileNames, Output) is equivalent to keymerge(KeyPos, FileNames, Output, []).
check(FileName) -> Reply
check(FileNames, Options) -> Reply

Types:
- Reply = {ok, [Result]} | {error, Reason}
- Result = {FileName, TermPosition, Term}
- TermPosition = int() > 1

Checks files for sortedness. If a file is not sorted, the first out-of-order element is returned. The first term on a file has position 1.

check(FileName) is equivalent to check([FileName], []).

keycheck(KeyPos, FileName) -> CheckReply
keycheck(KeyPos, FileNames, Options) -> Reply

Types:
- Reply = {ok, [Result]} | {error, Reason}
- Result = {FileName, TermPosition, Term}
- TermPosition = int() > 1

Checks files for sortedness. If a file is not sorted, the first out-of-order element is returned. The first term on a file has position 1.

keycheck(KeyPos, FileName) is equivalent to keycheck(KeyPos, [FileName], []).
filename

Erlang Module

The module *filename* provides a number of useful functions for analyzing and manipulating file names. These functions are designed so that the Erlang code can work on many different platforms with different formats for file names. With file name is meant all strings that can be used to denote a file. They can be short relative names like `foo.erl`, very long absolute name which include a drive designator and directory names like `D:\usr\local\bin\erl\lib\tools\foo.erl`, or any variations in between.

In Windows, all functions return file names with forward slashes only, even if the arguments contain back slashes. Use the `join/1` function to normalize a file name by removing redundant directory separators.

**Exports**

`absname(Filename) -> Absname`

Types:
- **Filename** = string() | [string()] | atom()
- **Absname** = string()

Converts a relative `Filename` and returns an absolute name. No attempt is made to create the shortest absolute name, because this can give incorrect results on file systems which allow links.

Examples include:
Assume (for UNIX) current directory `/usr/local`
Assume (for WIN32) current directory `D:/usr/local`

(for UNIX): `absname("foo")` -> `/usr/local/foo`
(for WIN32): `absname("foo")` -> `D:/usr/local/foo`
(for UNIX): `absname("../x")` -> `/usr/local/../x`
(for WIN32): `absname("../x")` -> `D:/usr/local/../x`
(for UNIX): `absname("/"")` -> `"/"
(for WIN32): `absname("/"")` -> `"D:/`

`absname(Filename, Directory) -> Absname`

Types:
- **Filename** = string() | [string()] | atom()
- **Directory** = string()
- **Absname** = string()
This function works like `absname/1`, except that the directory to which the file name should be made relative is given explicitly in the `Directory` argument.

`basename(Filename)`

Types:
- `Filename` = `string()` | `[string()]` | `atom()`

Returns the part of the `Filename` after the last directory separator, or the `Filename` itself if it has no separators.

Examples include:
- `basename("foo")` -> "foo"
- `basename("/usr/foo")` -> "foo"
- `basename("/")` -> []

`basename(Filename, Ext) -> string()`

Types:
- `Filename` = `Ext` = `string()` | `[string()]` | `atom()`

Returns the last component of `Filename` with the extension `Ext` stripped. Use this function if you want to remove an extension which might, or might not, be there. Use `rootname(basename(Filename))` if you want to remove an extension that exists, but you are not sure which one it is.

Examples include:
- `basename("~/.src/kalle.erl", ".erl")` -> "kalle"
- `basename("~/.src/kalle.beam", ".erl")` -> "kalle.beam"
- `basename("~/.src/kalle.old.erl", ".erl")` -> "kalle.old"
- `rootname(basename("~/.src/kalle.beam"))` -> "kalle"
- `rootname(basename("~/.src/kalle.beam"))` -> "kalle"

`dirname(Filename) -> string()`

Types:
- `Filename` = `string()` | `[string()]` | `atom()`

Returns the directory part of `Filename`.

Examples include:
- `dirname("/usr/src/kalle.erl")` -> "/usr/src"
- `dirname("kalle.erl")` -> ".

On Win32:
- `filename:dirname("\usr\src\kalle.erl")` -> "/usr/src"

`extension(Filename) -> string() | []`

Types:
- `Filename` = `string()` | `[string()]` | `atom()`

Given a file name string `Filename`, this function returns the file extension including the period. Returns an empty list if there is no extension.

Examples include:
extension("foo.erl") -> ".erl"
extension("beam.src/kalle") -> []

join(Components) -> string()

Types:
- Components = [string()]

Joins a list of file name Components with directory separators. If one of the elements in
the Components list includes an absolute path, for example "/xxx", the preceding
elements, if any, are removed from the result.
The result of the join function is “normalized”:
- There are no redundant directory separators.
- In Windows, all directory separators are forward slashes and the drive letter is in
  lower case.

Examples include:
- join("/usr/local", "bin") -> "/usr/local/bin"
- join(["/usr", "local", "bin"]) -> "/usr/local/bin"
- join(["a/b//c/""> "a/b/c"  (% On Windows only
- join(["B:a\\b///c/"] -> "b:a/b/c"  (% On Windows only

join(Name1, Name2) -> string()

Types:
- Name1 = Name2 = string()

Joins two file name components with directory separators. Equivalent to
join([Name1,Name2]).

nativename(Path) -> string()

Types:
- Path = string()

Converts a filename in Path to a form accepted by the command shell and native
applications on the current platform. On Windows, forward slashes will be converted to
backward slashes. On all platforms, the name will be normalized as done by join/1.
Example:
- (on UNIX) filename:nativename("/usr/local/bin") -> "/usr/local/bin"
- (on Win32) filename:nativename("/usr/local/bin") -> "\usr\local\bin"

pathtype(Path) -> absolute | relative | volumerelative

Returns one of absolute, relative, or volumerelative.

absolute  The path name refers to a specific file on a specific volume.
  Examples include:
relative  The path name is relative to the current working directory on the current volume.
Example:

foo/bar, ../src

volumerelative  The path name is relative to the current working directory on a specified volume, or it is a specific file on the current working volume.
Examples include:

In Windows
D:bar.erl, /bar/foo.erl
/temp

rootname(Filename) -> string()
rootname(Filename, Ext) -> string()

Types:
• Filename = Ext = string() | [string()] | atom()
rootname/1 returns all characters in Filename, except the extension.
rootname/2 works as rootname/1, except that the extension is removed only if it is Ext.
Examples include:

rootname("/beam.src/kalle") -> "/beam.src/kalle"
rootname("/beam.src/foo.erl") -> "/beam.src/foo"
rootname("/beam.src/foo.erl", ".erl") -> "/beam.src/foo"
rootname("/beam.src/foo.beam", ".erl") -> "/beam.src/foo.beam"

split(Filename) -> Components

Types:
• Filename = string() | [string()] | atom()
• Components = [string()]
Returns a list whose elements are the path components of Filename.
Examples include:

split("/usr/local/bin") -> ["/", "usr", "local", "bin"]
split("foo/bar") -> ["foo", "bar"]
split("a:\msdev\include") -> ["a:/", "msdev", "include"]

find_src(Module) -> {SourceFile, Options}
find_src(Module, Rules) -> {SourceFile, Options}

Types:
• Module = atom() | string()
• SourceFile = string()
• Options = [CompilerOption]
CompilerOption = \{i, string()\} | \{outdir, string()\} | \{d, atom()\}

Finds the source file name and compilation options for a compiled module. The result can be fed to compile:file/2 in order to compile the file again.

The Module argument, which can be a string or an atom, specifies either the module name or the path to the source code, with or without the ".erl" extension. In either case, the module must be known by the code manager, i.e. code:which/1 must succeed.

Rules describe how the source directory is found, when the object code directory is known. Each rule is of the form \{BinSuffix, SourceSuffix\} and is interpreted as follows: If the end of the directory name where the object is located matches BinSuffix, then the suffix of the directory name is replaced by SourceSuffix. If the source file is found in the resulting directory, then the function returns that location together with Options. Otherwise, the next rule is tried, and so on.

The function returns \{SourceFile, Options\}. SourceFile is the absolute path to the source file without the ".erl" extension. Options include the options which are necessary to compile the file with compile:file/2, but excludes options such as report or verbose which do not change the way code is generated. The paths in the \{outdir, Path\} and \{i, Path\} options are guaranteed to be absolute.
An implementation of ordered sets using Prof. Arne Andersson’s General Balanced Trees. This can be much more efficient than using ordered lists, for larger sets, but depends on the application. See notes below for details.

Complexity note

The complexity on set operations is bounded by either $O(|S|)$ or $O(|T| \cdot \log(|S|))$, where $S$ is the largest given set, depending on which is fastest for any particular function call. For operating on sets of almost equal size, this implementation is about 3 times slower than using ordered-list sets directly. For sets of very different sizes, however, this solution can be arbitrarily much faster; in practical cases, often between 10 and 100 times. This implementation is particularly suited for accumulating elements a few at a time, building up a large set (more than 100-200 elements), and repeatedly testing for membership in the current set.

As with normal tree structures, lookup (membership testing), insertion and deletion have logarithmic complexity.

Exports

empty()

Returns new, empty set.

Alias: new(), for compatibility with ‘sets’.

is_empty(S)

Returns ‘true’ if $S$ is an empty set, and ‘false’ otherwise.

size(S)

Returns the number of nodes in the set as an integer. Returns 0 (zero) if the set is empty.

singleton(X)

Returns a set containing only the element $X$.

is_member(X, S)
Returns ‘true’ if element X is a member of set S, and ‘false’ otherwise.

Alias: is_element(), for compatibility with ‘sets’.

**insert(X, S)**

Inserts element X into set S, returns the new set. Assumes that the element is not present in S.

**add(X, S)**

Adds element X to set S, returns the new set. If X is already an element in S, nothing is changed.

Alias: add_element(), for compatibility with ‘sets’.

**delete(X, S)**

Removes element X from set S, returns new set. Assumes that the element exists in the set.

Alias: del_element(), for compatibility with ‘sets’.

**balance(S)**

Rebalances the tree representation of S. Note that this is rarely necessary, but may be motivated when a large number of elements have been deleted from the tree without further insertions. Rebalancing could then be forced in order to minimise lookup times, since deletion only does not rebalance the tree.

**union(S1, S2)**

Returns a new set that contains each element that is in either S1 or S2 or both, and no other elements.

**union(Ss)**

Returns a new set that contains each element that is in at least one of the sets in the list Ss, and no other elements.

**intersection(S1, S2)**

Returns a new set that contains each element that is in both S1 and S2, and no other elements.

**intersection(Ss)**

Returns a new set that contains each element that is in all of the sets in the list Ss, and no other elements.

**difference(S1, S2)**

Returns a new set that contains each element in S1 that is not also in S2, and no other elements.

Alias: subtract(), for compatibility with ‘sets’.

**is_subset(S1, S2)**
Returns 'true' if each element in S1 is also a member of S2, and 'false' otherwise.

to_list(S)
Returns an ordered list of all elements in set S. The list never contains duplicates (of course).

from_list(List)
Creates a set containing all elements in List, where List may be unordered and contain duplicates.

from_ordset(L)
Turns an ordered-set list L into a set. The list must not contain duplicates.

take_smallest(S)
Returns {X, S1}, where X is the smallest element in set S, and S1 is the set S with element X deleted. Assumes that the set S is nonempty.

iterator(S)
Returns an iterator that can be used for traversing the entries of set S; see 'next'. The implementation of this is very efficient; traversing the whole set using 'next' is only slightly slower than getting the list of all elements using 'to_list' and traversing that. The main advantage of the iterator approach is that it does not require the complete list of all elements to be built in memory at one time.

next(T)
Returns {X, T1} where X is the smallest element referred to by the iterator T, and T1 is the new iterator to be used for traversing the remaining elements, or the atom 'none' if no elements remain.

filter(P, S)
Filters set S using predicate function P. Included for compatibility with 'sets'.

fold(F, A, S)
Folds function F over set S with A as the initial accumulator. Included for compatibility with 'sets'.

is_set(S)
Returns 'true' if S appears to be a set, and 'false' otherwise. Not recommended; included for compatibility with 'sets'.

gb_trees(3) [page 130], ordsets(3) [page 185], sets(3) [page 201]
gb_trees

Erlang Module

An efficient implementation of Prof. Arne Andersson's General Balanced Trees. These have no storage overhead compared to unbalanced binary trees, and their performance is in general better than AVL trees.

Data structure

Data structure:
- {Size, Tree}, where 'Tree' is composed of nodes of the form:
  - {Key, Value, Smaller, Bigger}, and the "empty tree" node:
    - nil.

There is no attempt to balance trees after deletions. Since deletions don’t increase the height of a tree, this should be O K.

Original balance condition $h(T) \leq \text{ceil}(c \times \log(|T|))$ has been changed to the similar (but not quite equivalent) condition $2^{-h(T)} \leq |T| \leq c$. This should also be O K.

Performance is comparable to the AVL trees in the Erlang book (and faster in general due to less overhead); the difference is that deletion works for these trees, but not for the book’s trees. Behaviour is logarithmic (as it should be).

Exports

empty()
Returns a new, empty tree.

is_empty(T)
Returns 'true' if T is an empty tree, and 'false' otherwise.

size(T)
Returns the number of nodes in the tree as an integer. Returns 0 (zero) if the tree is empty.

lookup(X, T)
Looks up key X in tree T; returns {value, V}, or 'none' if the key is not present.

get(X, T)
Retrieves the value stored with key X in tree T. Assumes that the key is present in the tree, crashes otherwise.

\texttt{insert(X, V, T)}

Inserts key X with value V into tree T; returns the new tree. Assumes that the key is not present in the tree, crashes otherwise.

\texttt{update(X, V, T)}

Updates key X to value V in tree T; returns the new tree. Assumes that the key is present in the tree.

\texttt{enter(X, V, T)}

Inserts key X with value V into tree T if the key is not present in the tree, otherwise updates key X to value V in T. Returns the new tree.

\texttt{delete(X, T)}

Removes key X from tree T; returns new tree. Assumes that the key is present in the tree, crashes otherwise.

\texttt{delete\_any(X, T)}

Removes key X from tree T if the key is present in the tree, otherwise does nothing; returns new tree.

\texttt{balance(T)}

Rebalances tree T. Note that this is rarely necessary, but may be motivated when a large number of entries have been deleted from the tree without further insertions. Rebalancing could then be forced in order to minimise lookup times, since deletion only does not rebalance the tree.

\texttt{is\_defined(X, T)}

Returns ‘true’ if key X is present in tree T, and ‘false’ otherwise.

\texttt{keys(T)}

Returns an ordered list of all keys in tree T.

\texttt{values(T)}

Returns a list of all values in tree T.

\texttt{to\_list(T)}

Returns an ordered list of (Key, Value) pairs for all keys in tree T.

\texttt{from\_orddict(L)}

turns an ordered list L of (Key, Value) pairs into a tree. The list must not contain duplicate keys.
take_smallest(T)

Returns \( (X, V, T1) \), where \( X \) is the smallest key in tree \( T \), \( V \) is the value associated with \( X \) in \( T \), and \( T1 \) is the tree \( T \) with key \( X \) deleted. Assumes that the tree \( T \) is nonempty.

iterator(T)

Returns an iterator that can be used for traversing the entries of tree \( T \); see ‘next’. The implementation of this is very efficient; traversing the whole tree using ‘next’ is only slightly slower than getting the list of all elements using ‘to_list’ and traversing that. The main advantage of the iterator approach is that it does not require the complete list of all elements to be built in memory at one time.

next(S)

Returns \( (X, V, S1) \) where \( X \) is the smallest key referred to by the iterator \( S \), and \( S1 \) is the new iterator to be used for traversing the remaining entries, or the atom ‘none’ if no entries remain.

**gen_event**

Erlang Module

A behaviour module for implementing event handling functionality. The OTP event handling model consists of a generic event manager process with an arbitrary number of event handlers which are added and deleted dynamically.

An event manager implemented using this module will have a standard set of interface functions and include functionality for tracing and error reporting. It will also fit into an OTP supervision tree. Refer to OTP Design Principles for more information.

Each event handler is implemented as a callback module exporting a pre-defined set of functions. The relationship between the behaviour functions and the callback functions can be illustrated as follows:

```
<table>
<thead>
<tr>
<th>gen_event module</th>
<th>Callback module</th>
</tr>
</thead>
<tbody>
<tr>
<td>gen_event:start</td>
<td>Module:init/1</td>
</tr>
<tr>
<td>gen_event:stop</td>
<td>Module:terminate/2</td>
</tr>
<tr>
<td>gen_event:notify</td>
<td>Module:handle_event/2</td>
</tr>
<tr>
<td>gen_event:sync_notify</td>
<td>Module:handle_call/2</td>
</tr>
<tr>
<td>gen_event:call</td>
<td>Module:handle_info/2</td>
</tr>
<tr>
<td>gen_event:delete_handler</td>
<td>Module:terminate/2</td>
</tr>
<tr>
<td>gen_event:swap_handler</td>
<td>Module1:terminate/2</td>
</tr>
<tr>
<td>gen_event:swap_sup_handler</td>
<td>Module2:init/1</td>
</tr>
<tr>
<td>gen_event:which_handlers</td>
<td>Module:code_change/3</td>
</tr>
</tbody>
</table>
```

Since each event handler is one callback module, an event manager will have several callback modules which are added and deleted dynamically. Therefore gen_event is more tolerant of callback module errors than the other behaviours. If a callback function for an installed event handler fails with Reason, or returns a bad value Term, the event manager will not fail. It will delete the event handler by calling the callback function.
The `sys` module can be used for debugging an event manager.

Note that an event manager does trap exit signals automatically.

Unless otherwise stated, all functions in this module fail if the specified event manager does not exist or if bad arguments are given.

**Exports**

start() -> Result
start(EventMgrName) -> Result
start_link() -> Result
start_link(EventMgrName) -> Result

Types:
- EventMgrName = \{local,Name\} | \{global,Name\}
- Name = atom()
- Result = \{ok,Pid\} | \{error,\{already_started,Pid\}\}
- Pid = pid()

Creates an event manager.

An event manager started using `start_link` is linked to the calling process. This function must be used if the event manager is included in a supervision tree. An event manager started using `start` is not linked to the calling process.

If `EventMgrName`=\{local,Name\}, the event manager is registered locally as `Name` using `register/2`. If `EventMgrName`=\{global,Name\}, the event manager is registered globally as `Name` using `global:register/2`. If no name is provided, the event manager is not registered.

If the event manager is successfully created the function returns \{ok,Pid\}, where Pid is the pid of the event manager. If there already exists a process with the specified `EventMgrName` the function returns \{error,\{already_started,Pid\}\}, where Pid is the pid of that process.

add_handler(EventMgrRef, Handler, Args) -> Result

Types:
- EventMgr = Name | \{Name,Node\} | \{global,Name\} | pid()
- Name = Node = atom()
- Handler = Module | \{Module,Id\}
- Module = atom()
- Id = term()
- Args = term()
- Result = ok | \{'EXIT',Reason\} | term()
- Reason = term()

Adds a new event handler to the event manager `EventMgrRef`. The event manager will call `Module:init/1` to initiate the event handler and its internal state.

`EventMgrRef` can be:
- the pid,
- Name, if the event manager is locally registered,
- \{(Name,Node)\}, if the event manager is locally registered at another node, or
- \{global,Name\}, if the event manager is globally registered.

Handler is the name of the callback module Module or a tuple \{(Module,Id)\}, where Id is any term. The \{(Module,Id)\} representation makes it possible to identify a specific event handler when there are several event handlers using the same callback module. Args is an arbitrary term which is passed as the argument to Module:init/1. If Module:init/1 returns a correct value, the event manager adds the event handler and this function returns ok. If Module:init/1 fails with Reason or returns an unexpected value Term, the event handler is ignored and this function returns \{'EXIT',Reason\} or Term, respectively.

```
add_sup_handler(EventMgrRef, Handler, Args) -> Result
```

Types:
- EventMgr = Name | \{(Name,Node)\} | \{global,Name\} | pid()
- Name = Node = atom()
- Handler = Module | \{(Module,Id)\}
- Module = atom()
- Id = term()
- Args = term()
- Result = ok | \{'EXIT',Reason\} | term()
- Reason = term()

Adds a new event handler in the same way as add_handler/3 but will also supervise the connection between the event handler and the calling process.

- If the calling process later terminates with Reason, the event manager will delete the event handler by calling Module:terminate/2 with \{stop,Reason\} as argument.
- If the event handler later is deleted, the event manager sends a message \{gen_event(EXIT,Handler,Reason)\} to the calling process. Reason is one of the following:
  - normal, if the event handler has been removed due to a call to delete_handler/3, or remove_handler has been returned by a callback function (see below).
  - shutdown, if the event handler has been removed because the event manager is terminating.
  - \{swapped,NewHandler,Pid\}, if the process Pid has replaced the event handler with another event handler NewHandler using a call to swap_handler/3 or swap_sup_handler/3.
  - a term, if the event handler is removed due to an error. Which term depends on the error.

See add_handler/3 for a description of the arguments and return values.

```
notify(EventMgrRef, Event) -> ok
sync_notify(EventMgrRef, Event) -> ok
```
Types:
- EventMgrRef = Name | {Name,Node} | {global,Name} | pid()
- Name = Node = atom()
- Event = term()

Sends an event notification to the event manager EventMgrRef. The event manager will call Module:handle_event/2 for each installed event handler to handle the event.

notify is asynchronous and will return immediately after the event notification has been sent. sync_notify is synchronous in the sense that it will return ok after the event has been handled by all event handlers.

See add_handler/3 for a description of EventMgrRef.

Event is an arbitrary term which is passed as one of the arguments to Module:handle_event/2.

notify will not fail even if the specified event manager does not exist, unless it is specified as Name.

call(EventMgrRef, Handler, Request) -> Result
call(EventMgrRef, Handler, Request, Timeout) -> Result

Types:
- EventMgrRef = Name | {Name,Node} | {global,Name} | pid()
- Name = Node = atom()
- Handler = Module | {Module,Id}
- Module = atom()
- Id = term()
- Request = term()
- Timeout = int() > 0 | infinity
- Result = Reply | {error,Error}
- Reply = term()
- Error = bad_module | {'EXIT',Reason} | term()
- Reason = term()

Makes a synchronous call to the event handler Handler installed in the event manager EventMgrRef by sending a request and waiting until a reply arrives or a timeout occurs. The event manager will call Module:handle_call/2 to handle the request.

See add_handler/3 for a description of EventMgrRef and Handler.

Request is an arbitrary term which is passed as one of the arguments to Module:handle_call/2.

Timeout is an integer greater than zero which specifies how many milliseconds to wait for a reply, or the atom infinity to wait indefinitely. Default value is 5000. If no reply is received within the specified time, the function call fails.

The return value Reply is defined in the return value of Module:handle_call/2. If the specified event handler is not installed, the function returns {error,bad_module}. If the callback function fails with Reason or returns an unexpected value Term, this function returns {error,{‘EXIT’,Reason}} or {error,Term}, respectively.

delete_handler(EventMgrRef, Handler, Args) -> Result

Types:
Determines an event handler from the event manager EventMgrRef. The event manager will call Module:terminate/2 to terminate the event handler.

See add_handler/3 for a description of EventMgrRef and Handler.

Args is an arbitrary term which is passed as one of the arguments to Module:terminate/2.

The return value is the return value of Module:terminate/2. If the specified event handler is not installed, the function returns {error, module_not_found}. If the callback function fails with Reason, the function returns {'EXIT', Reason}.

\[\text{swap_handler(EventMgrRef, \{Handler1, Args1\}, \{Handler2, Args2\})} \rightarrow \text{Result} \]

Types:

- EventMgrRef = Name \| \{Name, Node\} \| \{global, Name\} \| \text{pid()}
- Name = Node = atom()
- Handler1 = Handler2 = Module \| \{Module, Id\}
- Module = atom()
- Id = term()
- Args1 = Args2 = term()
- Result = ok \| \{error, Error\}
- Error = {'EXIT', Reason} \| term()
- Reason = term()

Replaces an old event handler with a new event handler in the event manager EventMgrRef.

See add_handler/3 for a description of the arguments.

First the old event handler Handler1 is deleted. The event manager calls Module1:terminate(Args1, ...), where Module1 is the callback module of Handler1, and collects the return value.

Then the new event handler Handler2 is added and initiated by calling Module2:init([Args2, Term]), where Module2 is the callback module of Handler2 and Term the return value of Module1:terminate/2. This makes it possible to transfer information from Handler1 to Handler2.

The new handler will be added even if the specified old event handler is not installed in which case Term=error, or if Module1:terminate/2 fails with Reason in which case Term={'EXIT', Reason}. The old handler will be deleted even if Module2:init/1 fails.

If there was a supervised connection between Handler1 and a process Pid, there will be a supervised connection between Handler2 and Pid instead.

If Module2:init/1 returns a correct value, this function returns ok. If Module2:init/1 fails with Reason or returns an unexpected value Term, this function returns \{error, {'EXIT', Reason} \} or \{error, Term\}, respectively.
swap_sup_handler(EventMgrRef, {Handler1,Args1}, {Handler2,Args2}) -> Result

Types:
- EventMgrRef = Name | {Name,Node} | {global,Name} | pid()
- Name = Node = atom()
- Handler1 = Handler2 = Module | {Module,Id}
- Module = atom()
- Id = term()
- Args1 = Args2 = term()
- Result = ok | {error,Error}
- Error = ['EXIT',Reason] | term()
- Reason = term()

Replaces an event handler in the event manager EventMgrRef in the same way as swap_handler/3 but will also supervise the connection between Handler2 and the calling process. See swap_handler/3 for a description of the arguments and return values.

which_handlers(EventMgrRef) -> [Handler]

Types:
- EventMgrRef = Name | {Name,Node} | {global,Name} | pid()
- Name = Node = atom()
- Handler = Module | {Module,Id}
- Module = atom()
- Id = term()

Returns a list of all event handlers installed in the event manager EventMgrRef. See add_handler/3 for a description of EventMgrRef and Handler.

stop(EventMgrRef) -> ok

Types:
- EventMgrRef = Name | {Name,Node} | {global,Name} | pid()
- Name = Node = atom()

Terminates the event manager EventMgrRef. Before terminating, the event manager will call Module:terminate(stop,...) for each installed event handler. See add_handler/3 for a description of the argument.

CALLBACK FUNCTIONS

The following functions should be exported from a gen_event callback module.
Exports

Module:init(InitArgs) -> {ok,State}

Types:
- InitArgs = Args | {Args,Term}
- Args = Term = term()
- State = term()

Whenever a new event handler is added to an event manager, this function is called to initialize the event handler.

If the event handler is added due to a call to \texttt{gen\_event:add\_handler/3} or \texttt{gen\_event:add\_sup\_handler/3}, \texttt{InitArgs} is the \texttt{Args} argument of these functions.

If the event handler is replacing another event handler due to a call to \texttt{gen\_event:swap\_handler/3} or \texttt{gen\_event:swap\_sup\_handler/3}, or due to a swap return tuple from one of the other callback functions, \texttt{InitArgs} is a tuple \{\texttt{Args},\texttt{Term}\} where \texttt{Args} is the argument provided in the function call/return tuple and \texttt{Term} is the result of terminating the old event handler, see \texttt{gen\_event:swap\_handler/3}.

The function should return \{\texttt{ok},\texttt{State}\} where \texttt{State} is the initial internal state of the event handler.

Module:handle\_event(Event, State) -> Result

Types:
- Event = term()
- State = term()
- Result = {ok,NewState} | \{swap\_handler,Args1,NewState,Handler2,Args2\} | remove\_handler
- NewState = term()
- Args1 = Args2 = term()
- Handler2 = Module2 | \{Module2,Id\}
- Module2 = atom()
- Id = term()

Whenever an event manager receives an event sent using \texttt{gen\_event:notify/2} or \texttt{gen\_event:sync\_notify/2}, this function is called for each installed event handler to handle the event.

\texttt{Event} is the \texttt{Event} argument of \texttt{notify/sync\_notify}.
\texttt{State} is the internal state of the event handler.

If the function returns \{\texttt{ok},\texttt{NewState}\} the event handler will remain in the event manager with the possible updated internal state \texttt{NewState}.

If the function returns \{\texttt{swap\_handler},\texttt{Args1},\texttt{NewState},\texttt{Handler2},\texttt{Args2}\} the event handler will be replaced by \texttt{Handler2} by first calling \texttt{Module:terminate(Args1,NewState)} and then \texttt{Module:init(Args2,Term)} where \texttt{Term} is the return value of \texttt{Module:terminate/2}. See \texttt{gen\_event:swap\_handler/3} for more information.

If the function returns \texttt{remove\_handler} the event handler will be deleted by calling \texttt{Module:terminate(remove\_handler,State)}.
Module:handle_call(Request, State) -> Result

Types:
- Request = term()
- State = term()
- Result = {ok,Reply,NewState} |
  | {swap_handler,Reply,Args1,NewState,Handler2,Args2} |
  | {remove_handler,Reply} |
- Reply = term()
- NewState = term()
- Args1 = Args2 = term()
- Handler2 = Module2 | {Module2,Id}
- Module2 = atom()
- Id = term()

Whenever an event manager receives a request sent using gen_event:call/3,4, this function is called for the specified event handler to handle the request. Request is the Request argument of call. State is the internal state of the event handler. The return values are the same as for handle_event/2 except they also contain a term Reply which is the reply given back to the client as the return value of call.

Module:handle_info(Info, State) -> Result

Types:
- Info = term()
- State = term()
- Result = {ok,NewState} |
  | {swap_handler,Args1,NewState,Handler2,Args2} | remove_handler |
- NewState = term()
- Args1 = Args2 = term()
- Handler2 = Module2 | {Module2,Id}
- Module2 = atom()
- Id = term()

This function is called for each installed event handler when an event manager receives any other message than an event or a synchronous request (or a system message). Info is the received message. See Module:handle_event/2 for a description of State and possible return values.

Module:terminate(Arg, State) -> term()

Types:
- Arg = Args | {stop,Reason} | stop | remove_handler |
   | {error,['EXIT',Reason]} | {error,Term} |
- Args = Reason = Term = term()
Whenever an event handler is deleted from an event manager, this function is called. It should be the opposite of Module:init/1 and do any necessary cleaning up.

If the event handler is deleted due to a call to gen_event:delete_handler, gen_event:swap_handler/3 or gen_event:swap_sup_handler/3, Arg is the Args argument of this function call.

Arg={[stop,Reason] if the event handler has a supervised connection to a process which has terminated with reason Reason.
Arg=stop if the event handler is deleted because the event manager is terminating.
Arg=remove_handler if the event handler is deleted because another callback function has returned remove_handler or [remove_handler,Reply].
Arg={[error,Term] if the event handler is deleted because a callback function returned an unexpected value Term, or Arg={[error,{'EXIT',Reason}] if a callback function failed.
State is the internal state of the event handler.
The function may return any term. If the event handler is deleted due to a call to gen_event:delete_handler, the return value of that function will be the return value of this function. If the event handler is to be replaced with another event handler due to a swap, the return value will be passed to the init function of the new event handler. Otherwise the return value is ignored.

Module:code_change(OldVsn, State, Extra) -> {ok, NewState}

Types:
- OldVsn = undefined | term()
- State = NewState = term()
- Extra = term()
This function is called for each installed event handler they should update the internal state due to code replacement, i.e. when the instruction {update,Module,Change,PrePurge,PostPurge,Modules where Change={[advanced,Extra] has been given to the release handler. See SASL User's Guide for more information.
OldVsn is the vsn attribute of the old version of the callback module Module, or undefined if no such attribute is defined.
State is the internal state of the event handler.
Extra is the same as in the [advanced,Extra] part of the update instruction.
The function should return {ok,NewState}, where NewState is the updated internal state.

SEE ALSO

supervisor(3), sys(3)
A behaviour module for implementing a finite state machine. A generic finite state machine process (gen_fsm) implemented using this module will have a standard set of interface functions and include functionality for tracing and error reporting. It will also fit into an OTP supervision tree. Refer to OTP Design Principles for more information.

A gen_fsm assumes all specific parts to be located in a callback module exporting a pre-defined set of functions. The relationship between the behaviour functions and the callback functions can be illustrated as follows:

```
gen_fsm module                     Callback module
---------------                     ---------------
gen_fsm:start_link                --> Module:init/1

gen_fsm:send_event                --> Module:StateName/2

gen_fsm:send_all_state_event     --> Module:handle_event/3

gen_fsm:sync_send_event          --> Module:StateName/3

gen_fsm:sync_send_all_state_event --> Module:handle_sync_event/4

-                             --> Module:handle_info/3
-                             --> Module:terminate/3
-                             --> Module:code_change/4
```

If a callback function fails or returns a bad value, the gen_fsm will terminate.
The sys module can be used for debugging a gen_fsm.

Note that a gen_fsm does not trap exit signals automatically, this must be explicitly initiated in the callback module.

Unless otherwise stated, all functions in this module fail if the specified gen_fsm does not exist or if bad arguments are given.
Exports

\[
\begin{align*}
\text{start}(\text{Module}, \text{Args}, \text{Options}) & \rightarrow \text{Result} \\
\text{start}(\text{FsmName}, \text{Module}, \text{Args}, \text{Options}) & \rightarrow \text{Result} \\
\text{start}_{\text{link}}(\text{Module}, \text{Args}, \text{Options}) & \rightarrow \text{Result} \\
\text{start}_{\text{link}}(\text{FsmName}, \text{Module}, \text{Args}, \text{Options}) & \rightarrow \text{Result}
\end{align*}
\]

Types:
- \(\text{FsmName} = \{\text{local}, \text{Name}\} \mid \{\text{global}, \text{Name}\}\)
- \(\text{Name} = \text{atom}\()\)
- \(\text{Module} = \text{atom}\()\)
- \(\text{Args} = \text{term}\()\)
- \(\text{Options} = \{\text{Option}\}\)
- \(\text{Option} = \{\text{debug}, \text{Dbgs}\} \mid \{\text{timeout}, \text{Time}\}\)
- \(\text{Dbgs} = \{\text{Dbg}\}\)
- \(\text{Dbg} = \text{trace} \mid \log \mid \text{statistics}\)
- \(\text{Result} = \{\text{ok}, \text{Pid}\} \mid \text{ignore} \mid \{\text{error}, \text{Error}\}\)
- \(\text{Pid} = \text{pid}\()\)
- \(\text{Error} = \{\text{already\_started}, \text{Pid}\} \mid \text{term}\)\

Creates a \text{gen\_fsm} process which calls \text{Module}:\text{init}/1 to initialize. To ensure a synchronized start-up procedure, this function does not return until \text{Module}:\text{init}/1 has returned.

A \text{gen\_fsm} started using \text{start}_{\text{link}} is linked to the calling process, this function must be used if the \text{gen\_fsm} is included in a supervision tree. A \text{gen\_fsm} started using \text{start} is not linked to the calling process.

If \text{FsmName}=\{\text{local}, \text{Name}\}, the \text{gen\_fsm} is registered locally as \text{Name} using \text{register}/2. If \text{FsmName}=\{\text{global}, \text{Name}\}, the \text{gen\_fsm} is registered globally as \text{Name} using \text{global}\_\text{register\_name}/2. If no name is provided, the \text{gen\_fsm} is not registered.

\text{Module} is the name of the callback module.

\text{Args} is an arbitrary term which is passed as the argument to \text{Module}:\text{init}/1.

If the option \{\text{timeout}, \text{Time}\} is present, the \text{gen\_fsm} is allowed to spend \text{Time} milliseconds initializing or it will be terminated and the start function will return \{\text{error}, \text{timeout}\}.

If the option \{\text{debug}, \text{Dbgs}\} is present, the corresponding \text{sys} function will be called for each item in \text{Dbgs}. Refer to \text{sys}(3) for more information.

If the \text{gen\_fsm} is successfully created and initialized the function returns \{\text{ok}, \text{Pid}\}, where \text{Pid} is the pid of the \text{gen\_fsm}. If there already exists a process with the specified \text{FsmName}, the function returns \{\text{error}, \{\text{already\_started}, \text{Pid}\}\} where \text{Pid} is the pid of that process.

If \text{Module}:\text{init}/1 fails with \text{Reason}, the function returns \{\text{error}, \text{Reason}\}. If \text{Module}:\text{init}/1 returns \{\text{stop}, \text{Reason}\} or \text{ignore}, the process is terminated and the function returns \{\text{error}, \text{Reason}\} or \text{ignore}, respectively.

\[
\text{send\_event}(\text{FsmRef}, \text{Event}) \rightarrow \text{ok}
\]

Types:
FsmRef = Name | \{Name,Node\} | \{global,Name\} | pid()
Name = Node = atom()
Event = term()

Sends an event asynchronously to the gen_fsm FsmRef and returns ok immediately. The gen_fsm will call Module:StateName/2 to handle the event, where StateName is the name of the current state of the gen_fsm.

FsmRef can be:
- the pid,
- Name, if the gen_fsm is locally registered,
- \{Name,Node\}, if the gen_fsm is locally registered at another node, or
- \{global,Name\}, if the gen_fsm is globally registered.

Event is an arbitrary term which is passed as one of the arguments to Module:StateName/2.

send_all_state_event(FsmRef, Event) -> ok
Types:
- FsmRef = Name | \{Name,Node\} | \{global,Name\} | pid()
- Name = Node = atom()
- Event = term()

Sends an event asynchronously to the gen_fsm FsmRef and returns ok immediately. The gen_fsm will call Module:handle_event/3 to handle the event.
See send_event/2 for a description of the arguments.

The difference between send_event and send_all_state_event is which callback function is used to handle the event. This function is useful when sending events that are handled the same way in every state, as only one handle_event clause is needed to handle the event instead of one clause in each state name function.

sync_send_event(FsmRef, Event) -> Reply
sync_send_event(FsmRef, Event, Timeout) -> Reply
Types:
- FsmRef = Name | \{Name,Node\} | \{global,Name\} | pid()
- Name = Node = atom()
- Event = term()
- Timeout = int() ≥ 0 | infinity
- Reply = term()
Sends an event to the gen_fsm FsmRef and waits until a reply arrives or a timeout occurs. The gen_fsm will call Module:StateName/3 to handle the event, where StateName is the name of the current state of the gen_fsm.

See send_event/2 for a description of FsmRef and Event.

Timeout is an integer greater than zero which specifies how many milliseconds to wait for a reply, or the atom infinity to wait indefinitely. Default value is 5000. If no reply is received within the specified time, the function call fails.

The return value Reply is defined in the return value of Module:StateName/3.

In the case where the gen_fsm terminates during the handling of the event and the caller is linked to the gen_fsm and trapping exits, the exit message is removed from the caller’s receive queue before the function call fails.

This behaviour is retained for backwards compatibility only and may change in the future. Note that if the gen_fsm crashes in between calls, a linked process must take care of the exit message anyway.

Warning: Under certain circumstances (e.g. FsmRef = \{Name,Node\}, and Node goes down) the exit message cannot be removed.

sync_send_all_state_event(FsmRef, Event) -> Reply
sync_send_all_state_event(FsmRef, Event, Timeout) -> Reply

Types:
- FsmRef = Name | \{Name,Node\} | \{global,Name\} | pid()
- Name = Node = atom()
- Event = term()
- Timeout = int(0) | infinity
- Reply = term()

Sends an event to the gen_fsm FsmRef and waits until a reply arrives or a timeout occurs. The gen_fsm will call Module:handle_event/3 to handle the event.

See send_event/2 for a description of FsmRef and Event. See sync_send_event/3 for a description of Timeout and Reply.

See send_all_state_event/3 for a discussion about the difference between sync_send_event and sync_send_all_state_event.

reply(Caller, Reply) -> true

Types:
- Caller - see below
- Reply = term()

This function can be used by a gen_fsm to explicitly send a reply to a client process that called sync_send_event or sync_send_all_state_event, when the reply cannot be defined in the return value of Module:State/3 or Module:handle_sync_event/4.

Caller must be the From argument provided to the callback function. Reply is an arbitrary term, which will be given back to the client as the return value of sync_send_event or sync_send_all_state_event.
CALLBACK FUNCTIONS

The following functions should be exported from a `gen_fsm` callback module. In the description, the expression `state name` is used to denote a state of the state machine, `state data` is used to denote the internal state of the Erlang process which implements the state machine.

Exports

Module:init(Args) -> Result

Types:
- `Args = term()`
- `Return = {ok,StateName,StateData} | {ok,StateName,StateData,Timeout} | {stop,Reason} | ignore`
- `StateName = atom()`
- `StateData = term()`
- `Timeout = int() > 0 | infinity`
- `Reason = term()`

Whenever a `gen_fsm` is started using `gen_fsm:start/3,4` or `gen_fsm:start_link/3,4`, this function is called by the new process to initialize. `Args` is the `Args` argument provided to the start function.

If initialization is successful, the function should return `{ok,StateName,StateData}` or `{ok,StateName,StateData,Timeout}`, where `StateName` is the initial state name and `StateData` the initial state data of the `gen_fsm`.

If an integer timeout value is provided, a timeout will occur unless an event or a message is received within `Timeout` milliseconds. A timeout is represented by the atom `timeout` and should be handled by the `Module:StateName/2` callback functions. The atom `infinity` can be used to wait indefinitely, this is the default value.

If something goes wrong during the initialization the function should return `{stop,Reason}`, where `Reason` is any term, or `ignore`.

Module:StateName(Event, StateData) -> Result

Types:
- `Event = timeout | term()`
- `StateData = term()`
- `Result = {next_state,NextStateName,NewStateData} | {next_state,NextStateName,NewStateData,Timeout} | {stop,Reason,NewStateData} | ignore`
- `NextStateName = atom()`
- `NewStateData = term()`
- `Timeout = int() > 0 | infinity`
- `Reason = term()`
There should be one instance of this function for each possible state name. Whenever a gen_fsm receives an event sent using gen_fsm:send_event/2, the instance of this function with the same name as the current state name StateName is called to handle the event. It is also called if a timeout occurs.

Event is either the atom timeout, if a timeout has occurred, or the Event argument provided to send_event.

StateData is the state data of the gen_fsm.

If the function returns \{next_state, NextStateName, NewStateData\} or \{next_state, NextStateName, NewStateData, Timeout\}, the gen_fsm will continue executing with the current state name set to NextStateName and with the possibly updated state data NewStateData. See Module:init/1 for a description of Timeout.

If the function returns \{stop, Reason, NewStateData\}, the gen_fsm will call Module:terminate(Reason, NewStateData) and terminate.

```
Module:handle_event(Event, StateName, StateData) -> Result
Types:
  • Event = term()
  • StateName = atom()
  • StateData = term()
  • Result = \{next_state, NextStateName, NewStateData\} | \{next_state, NextStateName, NewStateData, Timeout\} |
  1 \{stop, Reason, NewStateData\}
  1 NextStateName = atom()
  1 NewStateData = term()
  1 Timeout = int() > 0 | infinity
  1 Reason = term()

Whenever a gen_fsm receives an event sent using gen_fsm:send_all_state_event/2, this function is called to handle the event.

StateName is the current state name of the gen_fsm.

See Module:StateName/2 for a description of the other arguments and possible return values.

Module:StateName(Event, From, StateData) -> Result
Types:
  • Event = term()
  • From = \{pid(), Tag\}
  • StateData = term()
  • Result = \{reply, Reply, NextStateName, NewStateData\} | \{reply, Reply, NextStateName, NewStateData, Timeout\} |
  1 \{next_state, NextStateName, NewStateData\} | \{next_state, NextStateName, NewStateData, Timeout\} |
  1 \{stop, Reason, Reply, NewStateData\} | \{stop, Reason, NewStateData\}
  1 Reply = term()
  1 NextStateName = atom()
  1 NewStateData = term()
  1 Timeout = int() > 0 | infinity
```
There should be one instance of this function for each possible state name. Whenever a gen_fsm receives an event sent using gen_fsm:sync_send_event/2,3, the instance of this function with the same name as the current state name StateName is called to handle the event.

Event is the Event argument provided to sync_send_event.
From is a tuple {Pid,Tag} where Pid is the pid of the process which called sync_send_event and Tag is a unique tag.
StateData is the state data of the gen_fsm.

If the function returns {reply,Reply,NextStateName,NewStateData} or {reply,Reply,NextStateName,NewStateData,Timeout}, Reply will be given back to From as the return value of sync_send_event. The gen_fsm then continues executing with the current state name set to NextStateName and with the possibly updated state data NewStateData. See Module:init/1 for a description of Timeout.

If the function returns {next_state,NextStateName,NewStateData} or {next_state,NextStateName,NewStateData,Timeout}, the gen_fsm will continue executing in NextStateName with NewStateData. Any reply to From must be given explicitly using gen_fsm:reply/2.

If the function returns {stop,Reason,Reply,NewStateData}, Reply will be given back to From. If the function returns {stop,Reason,NewStateData}, any reply to From must be given explicitly using gen_fsm:reply/2. The gen_fsm will then call Module:terminate(Reason,NewStateData) and terminate.

Whenever a gen_fsm receives an event sent using gen_fsm:sync_send_all_state_event/2,3, this function is called to handle the event. StateName is the current state name of the gen_fsm.
See Module:StateName/3 for a description of the other arguments and possible return values.

Module:handle_sync_event(Event, From, StateName, StateData) -> Result

Types:
• Event = term()
• From = {pid(),Tag}
• StateName = atom()
• StateData = term()
• Result = {reply,Reply,NextStateName,NewStateData} | {reply,Reply,NextStateName,NewStateData,Timeout}
  | {next_state,NextStateName,NewStateData} | {next_state,NextStateName,NewStateData,Timeout}
  | {stop,Reason,Reply,NewStateData} | {stop,Reason,NewStateData}
• Reply = term()
• NextStateName = atom()
• NewStateData = term()
• Timeout = int() > 0 | infinity
• Reason = term()
Types:
- **Info** = term()
- **StateName** = atom()
- **StateData** = term()
- **Result** = {next_state, NextStateName, NewStateData} | {stop, Reason, NewStateData, Timeout}
  - next_state = atom()
  - NextStateName = atom()
  - NewStateData = term()
  - Timeout = int() > 0 | infinity
  - Reason = normal | term()
This function is called by a gen_fsm when it receives any other message than a synchronous or asynchronous event (or a system message).
Info is the received message.
See Module:StateName/2 for a description of the other arguments and possible return values.

**Module:terminate(Reason, StateName, StateData)**

Types:
- **Reason** = normal | shutdown | term()
- **StateName** = atom()
- **StateData** = term()
This function is called by a gen_fsm when it is about to terminate. It should be the opposite of Module:init/1 and do any necessary cleaning up. When it returns, the gen_fsm terminates with Reason. The return value is ignored.
Reason is a term denoting the stop reason, StateName is the current state name, and StateData is the state data of the gen_fsm.
Reason depends on why the gen_fsm is terminating. If it is because another callback function has returned a stop tuple {stop, ...}, Reason will have the value specified in that tuple. If it is due to a failure, Reason is the error reason.
If the gen_fsm is part of a supervision tree and is ordered by its supervisor to terminate, this function will be called with Reason=shutdown if the following conditions apply:  
- the gen_fsm has been set to trap exit signals, and  
- the shutdown strategy as defined in the supervisor's child specification is an integer timeout value, not brutal_kill.
Otherwise, the gen_fsm will be immediately terminated.
Note that for any other reason than normal or shutdown, the gen_fsm is assumed to terminate due to an error and an error report is issued using error_logger:format/2.

**Module:code_change(OldVsn, StateName, StateData, Extra) -> {ok, NextStateName, NewStateData}**

Types:
- **OldVsn** = undefined | term()
- **StateName** = NextStateName = atom()
This function is called by a `gen_fsm` when it should update its state data due to a code replacement, i.e., when the instruction

```
{update, Module, Change, PrePurge, PostPurge, Modules} where Change={advanced, Extra} has been given to the release handler. See SASL User’s Guide for more information.
```

`OldVsn` is the `vsn` attribute of the old version of the callback module `Module`, or undefined if no such attribute is defined.

`StateName` is the current state name and `StateData` the state data of the `gen_fsm`.

`Extra` is the same as in the `{advanced, Extra}` part of the update instruction.

The function should return the new current state name and updated state data.

**SEE ALSO**

`supervisor(3)`, `sys(3)`
A behaviour module for implementing the server of a client-server relation. A generic server process (gen_server) implemented using this module will have a standard set of interface functions and include functionality for tracing and error reporting. It will also fit into an OTP supervision tree. Refer to OTP Design Principles for more information.

A gen_server assumes all specific parts to be located in a callback module exporting a pre-defined set of functions. The relationship between the behaviour functions and the callback functions can be illustrated as follows:

```
gen_server module          Callback module
-----------------          --------------------
gen_server:start          ----> Module:init/1

gen_server:call

gen_server:multi_call     ----> Module:handle_call/3

gen_server:cast

gen_server:abcast         ----> Module:handle_cast/2

-                             ----> Module:handle_info/2

-                             ----> Module:terminate/2

-                             ----> Module:code_change/3
```

If a callback function fails or returns a bad value, the gen_server will terminate.

The sys module can be used for debugging a gen_server.

Note that a gen_server does not trap exit signals automatically, this must be explicitly initiated in the callback module.

Unless otherwise stated, all functions in this module fail if the specified gen_server does not exist or if bad arguments are given.

Exports

```
start(Module, Args, Options) -> Result
start(ServerName, Module, Args, Options) -> Result
start_link(Module, Args, Options) -> Result
start_link(ServerName, Module, Args, Options) -> Result
```

Types:
- ServerName = {local, Name} | {global, Name}
- Name = atom()
- Module = atom()
- Args = term()
- Options = [Option]
  - Option = (debug,Dbgs) | (timeout,Time)
  - Dbgs = [Dbg]
  - Dbg = trace | log | statistics | {log_to_file,FileName} | {install,{Func,FuncState}}
- Result = {ok,Pid} | ignore | {error,Error}
- Pid = pid()
- Error = {already_started,Pid} | term()

Creates a gen_server process which calls Module:init/1 to initialize. To ensure a synchronized start-up procedure, this function does not return until Module:init/1 has returned.

A gen_server started using start_link is linked to the calling process, this function must be used if the gen_server is included in a supervision tree. A gen_server started using start is not linked to the calling process.

If ServerName=local,Name the gen_server is registered locally as Name using register/2. If ServerName=global,Name the gen_server is registered globally as Name using global:register_name/2. If no name is provided, the gen_server is not registered.

Module is the name of the callback module.

Args is an arbitrary term which is passed as the argument to Module:init/1.

If the option {timeout,Time} is present, the gen_server is allowed to spend Time milliseconds initializing or it will be terminated and the start function will return {error,timeout}.

If the option {debug,Dbgs} is present, the corresponding sys function will be called for each item in Dbgs. Refer to sys(3) for more information.

If the gen_server is successfully created and initialized the function returns {ok,Pid}, where Pid is the pid of the gen_server. If there already exists a process with the specified ServerName the function returns {error,{already_started,Pid}}, where Pid is the pid of that process.

If Module:init/1 fails with Reason, the function returns {error,Reason}. If Module:init/1 returns {stop,Reason} or ignore, the process is terminated and the function returns {error,Reason} or ignore, respectively.

call(ServerRef, Request) -> Reply

call(ServerRef, Request, Timeout) -> Reply

Types:
- ServerRef = Name | {Name,Node} | {global,Name} | pid()
- Name = Node = atom()
- Request = term()
- Timeout = int() > 0 | infinity
- Reply = term()
 Makes a synchronous call to the gen_server ServerRef by sending a request and waiting until a reply arrives or a timeout occurs. The gen_server will call Module:handle_call/3 to handle the request.

ServerRef can be:

- the pid,
- Name, if the gen_server is locally registered,
- [Name,Node], if the gen_server is locally registered at another node, or
- [global,Name], if the gen_server is globally registered.

Request is an arbitrary term which is passed as one of the arguments to Module:handle_call/3.

Timeout is an integer greater than zero which specifies how many milliseconds to wait for a reply, or the atom infinity to wait indefinitely. Default value is 5000. If no reply is received within the specified time, the function call fails.

The return value Reply is defined in the return value of Module:handle_call/3.

In the case where the gen_server terminates during the handling of the request and the client is linked to the gen_server and trapping exits, the exit message is removed from the client's receive queue before the function call fails.

This behaviour is retained for backwards compatibility only and may change in the future. Note that if the gen_server crashes in between calls, the client must take care of the exit message anyway.

Warning: Under certain circumstances (e.g. ServerRef = {[Name,Node], and Node goes down}) the exit message cannot be removed.

multi_call(Name, Request) -> Result
multi_call(Nodes, Name, Request) -> Result
multi_call(Nodes, Name, Request, Timeout) -> Result

Types:

- Nodes = [Node]
- Node = atom()
- Name = atom()
- Request = term()
- Timeout = int() >= 0 | infinity
- Result = {[Replies,BadNodes]}
- Replies = [{Node,Reply}]
- Reply = term()
- BadNodes = [Node]

Makes a synchronous call to all gen_servers locally registered as Name at the specified nodes by first sending a request to every node and then waiting for the replies. The gen_servers will call Module:handle_call/3 to handle the request.

The function returns a tuple {Replies,BadNodes} where Replies is a list of {Node,Reply} and BadNodes is a list of node that either did not exist, or where the gen_server Name did not exist or did not reply.

Nodes is a list of node names to which the request should be sent. Default value is the list of all known nodes [node()|nodes()].

Name is the locally registered name of each gen_server.
Request is an arbitrary term which is passed as one of the arguments to Module:handle_call/3.

Timeout is an integer greater than zero which specifies how many milliseconds to wait for each reply, or the atom infinity to wait indefinitely. Default value is infinity. If no reply is received from a node within the specified time, the node is added to BadNodes.

When a reply Reply is received from the gen_server at a node Node, {Node,Reply} is added to Replies. Reply is defined in the return value of Module:handle_call/3.

Warning:
If one of the nodes is running Erlang/OTP R6B or older, and the gen_server is not started when the requests are sent, but starts within 2 seconds, this function waits the whole Timeout, which may be infinity.
This problem does not exist if all nodes are running Erlang/OTP R7B or later.

This function does not read out any exit messages like call/2,3 does.
The previously undocumented functions safe_multi_call/2,3,4 were removed in OTP R7B/Erlang 5.0 since this function is now safe, except in the case mentioned above.

**cast**

ServerRef, Request) -> ok

Types:
- ServerRef = Name | {Name,Node} | {global,Name} | pid()
- Name = Node = atom()
- Request = term()

Sends an asynchronous request to the gen_server ServerRef and returns ok immediately. The gen_server will call Module:handle_cast/2 to handle the request. See call/2,3 for a description of ServerRef.

Request is an arbitrary term which is passed as one of the arguments to Module:handle_cast/2.

**abcast**

Name, Request) -> abcast

Nodes, Name, Request) -> abcast

Types:
- Nodes = [Node]
- Node = atom()
- Name = atom()
- Request = term()

Sends an asynchronous request to the gen_servers locally registered as Name at the specified nodes. The function returns immediately and ignores nodes that does not exist, or where the gen_server Name does not exist. The gen_servers will call Module:handle_cast/2 to handle the request. See multi_call/2,3,4 for a description of the arguments.
reply(Client, Reply) -> true

Types:
- Client - see below
- Reply = term()

This function can be used by a gen_server to explicitly send a reply to a client that called call or multi_call, when the reply cannot be defined in the return value of Module:handle_call/3.

Client must be the From argument provided to the callback function. Reply is an arbitrary term, which will be given back to the client as the return value of call or multi_call.

CALLBACK FUNCTIONS

The following functions should be exported from a gen_server callback module.

Exports

Module:init(Args) -> Result

Types:
- Args = term()
- Result = {ok,State} | {ok,State,Timeout} |
  {stop,Reason} | ignore
- State = term()
- Timeout = int() >= 0 | infinity
- Reason = term()

Whenever a gen_server is started using gen_server:start/3,4 or gen_server:start_link/3,4, this function is called by the new process to initialize. Args is the Args argument provided to the start function.

If the initialization is successful, the function should return {ok,State} or {ok,State,Timeout}, where State is the internal state of the gen_server.

If an integer timeout value is provided, a timeout will occur unless a request or a message is received within Timeout milliseconds. A timeout is represented by the atom timeout which should be handled by the handle_info/2 callback function. The atom infinity can be used to wait indefinitely, this is the default value.

If something goes wrong during the initialization the function should return {stop,Reason} where Reason is any term, or ignore.

Module:handle_call(Request, From, State) -> Result

Types:
- Request = term()
- From = {pid(),Tag}
- State = term()
- Result = {reply,Reply,NewState} | {reply,Reply,NewState,Timeout}
Whenever a gen_server receives a request sent using gen_server:call/2,3 or gen_server:multi_call/2,3,4, this function is called to handle the request. Request is the Request argument provided to call or multi_call. From is a tuple {Pid,Tag} where Pid is the pid of the client and Tag is a unique tag. State is the internal state of the gen_server.

- If the function returns {reply,Reply,NewState} or {reply,Reply,NewState,Timeout}, Reply will be given back to From as the return value of call or included in the return value of multi_call. The gen_server then continues executing with the possibly updated internal state NewState. See Module:init/1 for a description of Timeout.
- If the functions returns {noreply,NewState} or {noreply,NewState,Timeout}, the gen_server will continue executing with NewState. Any reply to From must be given explicitly using gen_server:reply/2.
- If the function returns {stop,Reason,Reply,NewState}, Reply will be given back to From. If the function returns {stop,Reason,NewState}, any reply to From must be given explicitly using gen_server:reply/2. The gen_server will then call Module:terminate(Reason,NewState) and terminate.

Module:handle_cast(Request, State) -> Result

Types:
- Request = term()
- State = term()
- Result = {noreply,NewState} | {noreply,NewState,Timeout} | {stop,Reason,NewState} | {stop,Reason,NewState,Timeout}
- NewState = term()
- Timeout = int() > 0 | infinity
- Reason = term()

Whenever a gen_server receives a request sent using gen_server:cast/2 or gen_server:abcast/2,3, this function is called to handle the request. See Module:handle_call/3 for a description of the arguments and possible return values.

Module:handle_info(Info, State) -> Result

Types:
- Info = timeout | term()
- State = term()
- Result = {noreply,NewState} | {noreply,NewState,Timeout} | {stop,Reason,NewState} | {stop,Reason,NewState,Timeout}
- NewState = term()
- Timeout = int()>=0 | infinity
- Reason = normal | term()

This function is called by a gen_server when a timeout occurs or when it receives any other message than a synchronous or asynchronous request (or a system message).

Info is either the atom timeout, if a timeout has occurred, or the received message.

See Module:handle_call/3 for a description of the other arguments and possible return values.

Module:terminate(Reason, State)

Types:
- Reason = normal | shutdown | term()
- State = term()

This function is called by a gen_server when it is about to terminate. It should be the opposite of Module:init/1 and do any necessary cleaning up. When it returns, the gen_server terminates with Reason. The return value is ignored.

Reason is a term denoting the stop reason and State is the internal state of the gen_server.

Reason depends on why the gen_server is terminating. If it is because another callback function has returned a stop tuple {stop,...}, Reason will have the value specified in that tuple. If it is due to a failure, Reason is the error reason.

If the gen_server is part of a supervision tree and is ordered by its supervisor to terminate, this function will be called with Reason=shutdown if the following conditions apply:

- the gen_server has been set to trap exit signals, and
- the shutdown strategy as defined in the supervisor's child specification is an integer timeout value, not brutal kill.

Otherwise, the gen_server will be immediately terminated.

Note that for any other reason than normal or shutdown, the gen_server is assumed to terminate due to an error and an error report is issued using error_logger:format/2.

Module:code_change(OldVsn, State, Extra) -> {ok, NewState}

Types:
- OldVsn = undefined | term()
- State = NewState = term()
- Extra = term()

This function is called by a gen_server when it should update its internal state due to code replacement, i.e. when the instruction
(update,Module,Change,PrePurge,PostPurge,Modules) where Change=advanced,Extra has been given to the release handler. See SASL User's Guide for more information.

OldVsn is the vsn attribute of the old version of the callback module Module, or undefined if no such attribute is defined.

State is the internal state of the gen_server.

Extra is the same as in the {advanced,Extra} part of the update instruction.

The function should return the updated internal state.
SEE ALSO

supervisor(3), sys(3)
This module provides an interface to standard Erlang IO servers. The output functions all return \texttt{ok} if they are successful, or exit if they are not. In the following description, a parameter within square brackets means that that parameter is optional. [\texttt{IoDevice,}] is such an example. If included, it must be the Pid of a process which handles the IO protocols. This is often the \texttt{IoDevice} returned by \texttt{file:open/2} (see \texttt{file}). For a description of the I/O protocols refer to Armstrong, Virding and Williams, ‘Concurrent Programming in Erlang’, Chapter 13.

\textbf{Exports}

\begin{description}
\item[put_chars([\texttt{IoDevice,}] Chars)]
Writes the characters \texttt{Chars} to the standard output (\texttt{IoDevice}). \texttt{Chars} is a list of characters. The list is not necessarily flat.
\item[nl([\texttt{IoDevice}])]\texttt{nl} writes new line to the standard output (\texttt{IoDevice}).
\item[get_chars([\texttt{IoDevice,}] Prompt, Count)]
Gets \texttt{Count} characters from standard input (\texttt{IoDevice}), prompting it with \texttt{Prompt}. It returns:
\begin{itemize}
\item \texttt{ListOfChars} Returns the input characters, if they are less than \texttt{Count}.
\item \texttt{eof} End of file was encountered.
\end{itemize}
\item[get_line([\texttt{IoDevice,}] Prompt)]
Gets a line from the standard input (\texttt{IoDevice}), prompting it with \texttt{Prompt}. It returns:
\begin{itemize}
\item \texttt{ListOfChars} The characters in the line terminated by a LF unless the line read was the last line of the file and was not terminated by LF.
\item \texttt{eof} End of file was encountered.
\end{itemize}
\item[write([\texttt{IoDevice,}] Term)]
\texttt{write} writes the term \texttt{Term} to the standard output (\texttt{IoDevice}).
\item[read([\texttt{IoDevice,}] Prompt)]
Reads the standard input (\texttt{IoDevice}).
Reads a term from the standard input (IoDevice), prompting it with Prompt. It returns:

{ok, Term} The parsing was successful.
{error, ErrorInfo} The parsing failed.
{eof} End of file was encountered.

fwrite(Format)
format(Format)

Equivalent to fwrite(Format, []).

fwrite([IoDevice,] Format, Arguments)
format([IoDevice,] Format, Arguments)

Writes the list of items in Arguments on the standard output (IoDevice) in accordance with Format. Format is a list of plain characters which are copied to the output device, and control sequences which cause the arguments to be printed. If Format is an atom, it is first converted to a list with the aid of atom_to_list/1. Arguments is the list of items to be printed.

> io:fwrite("Hello world!\n", []).
Hello world
ok

The general format of a control sequence is \~F.P.PadC. The character C determines the type of control sequence to be used, F and P are optional numeric arguments. If F, P, or Pad is *, the next argument in Arguments is used as the numeric value of F or P.

F is the field width of the printed argument. A negative value means that the argument will be left justified within the field, otherwise it will be right justified. If no field width is specified, the required print width will be used. If the field width specified is too small, then the whole field will be filled with * characters.

P is the precision of the printed argument. A default value is used if no precision is specified. The interpretation of precision depends on the control sequences. Unless otherwise specified, the argument within is used to determine print width.

Pad is the padding character. This is the character used to pad the printed representation of the argument so that it conforms to the specified field width and precision. Only one padding character can be specified and, whenever applicable, it is used for both the field width and precision. The default padding character is ' ' (space).

The following control sequences are available:

\~ The character \~ is written.

c The argument is a number that will be interpreted as an ASCII code. The precision is the number of times the character is printed and it defaults to the field width, which in turn defaults to one. The following example illustrates:

> io:fwrite("|\~10.5c|\~10.5c|\~5c|\n", [$a, $b, $c]).
| aaaaa|aaaaa |ccccc|
ok

f The argument is a float which is written as [-]ddd.ddd, where the precision is the number of digits after the decimal point. The default precision is 6.
The argument is a float which is written as \([-\]d.ddde+-ddd\), where the precision is the number of digits written. The default precision is 6.

The argument is a float which is written as f, if it is \(> 0.1\), and \(< 10^{-4}\). Otherwise, it is written as e. The precision is the number of significant digits. It defaults to 6. There must always be a sufficient number of digits for printing a correct floating point representation of the argument.

Prints the argument with the string syntax. The argument is a list of character codes (possibly not a flat list), or an atom. The characters are printed without quotes. In this format, the printed argument is truncated to the given precision and field width.

This format can be used for printing any object and truncating the output so it fits a specified field:

> io:fwrite("\(~10w\)\n", [{hey, hey, hey}]).
|**********|
ok

> io:fwrite("\(~10s\)\n", [io_lib:write({hey, hey, hey})]).
[{hey, hey, h]
ok

Writes data with the standard syntax. This is used to output Erlang terms. Atoms are printed within quotes if they contain embedded non-printable characters, and floats are printed in the default g format.

Writes the data with standard syntax in the same way as ~w, but breaks terms whose printed representation is longer than one line into many lines and indents each line sensibly. It also tries to detect lists of printable characters and to output these as strings. For example:

> T = [{attributes,[[{id,age,1.500000},{mode,explicit},
{typename,"INTEGER"}],
[{id,cho},{mode,explicit},{typename,'Cho'}]]},
{typename,'Person'},
{tag,{'PRIVATE',3}},
{mode,implicit}].
...

> io:fwrite("~w\n", [T]).
[[{attributes,[[{id,age,1.500000},{mode,explicit},{typename,[73,78,84,69,71,69,82]}],
{{id,cho},{mode,explicit},{typename,'Cho'}}]},
{typename,'Person'},
{tag,{'PRIVATE',3}},{mode,implicit}]]
ok

> io:fwrite("~p\n", [T]).
[[{attributes,[[{id,age,1.500000},
{mode,explicit}],
{typename,"INTEGER"}],
[{{id,cho},{mode,explicit},{typename,'Cho'}}]},
{typename,'Person'},
{tag,{'PRIVATE',3}},{mode,implicit}]]
ok

The field width specifies the maximum line length. It defaults to 80. The precision specifies the initial indentation of the term. It defaults to the number of characters printed on this line in the same call to io:fwrite or io:format. For example, using T above:
> io:fwrite("Here T = \"p\"n", [T]).
Here T = [{attributes,[[{id,age,1.500000},
   {mode,explicit},
   {typename,"INTEGER"}],
   [{id,cho},{mode,explicit}],
   {typename,'Cho'}]},
   {typename,'Person'},
   {tag,{'PRIVATE',3}},
   {mode,implicit}]
ok

w Writes data in the same way as ~w, but takes an extra argument which is the maximum depth to which terms are printed. Anything below this depth is replaced with .... For example, using T above:

> io:fwrite("W\"n", [T,9]).
[{attributes,[[{id,age,1.500000},{mode,explicit},{typename|
   ...}],[[{id,cho},{mode|...},{...}]],{typename,'Person'},{t
ag,{'PRIVATE',3}},{mode,implicit}]}
ok

If the maximum depth has been reached, then it is impossible to read in the resultant output. Also, the |... form in a tuple denotes that there are more elements in the tuple but these are below the print depth.

p Writes data in the same way as ~p, but takes an extra argument which is the maximum depth to which terms are printed. Anything below this depth is replaced with .... For example:

> io:fwrite("P\"n", [T,9]).
[{attributes,[[{id,age,1.500000},{mode,explicit},
   {typename|...}],[[{id,cho},{mode|...},{...}]],{typename,'Person'},{t
ag,{'PRIVATE',3}},{mode,implicit}]}
ok

n Writes a new line.
i Ignores the next term.

Returns:

ok The formatting succeeded.

If an error occurs, there is no output. For example:

> io:fwrite("s ~w ~i ~w ~c ~n",['abc def', 'abc def',
   {foo, 1},{foo, 1}, 65]).
abc def 'abc def' {foo, 1} A
ok
> io:fwrite("s", [65]).
** exited: {badarg,[[io(format,[<0.21.0>,"s","A"]],[
erl_eval:expr,3],
erl_eval:exprs,4],
shell,eval_loop,2]} **
In this example, an attempt was made to output the single character ’65’ with the aid of
the string formatting directive “~s”.

The two functions fwrite and format are identical. The old name format has been
retained for backwards compatibility, while the new name fwrite has been added as a
logical complement to fread.

fwrite([IoDevice,] Prompt, Format)

Reads characters from the standard input (IoDevice), prompting it with Prompt.
Interprets the characters in accordance with Format. Format is a list of control
sequences which directs the interpretation of the input.

Format may contain:

- White space characters (SPACE, TAB and NEWLINE) which cause input to be
  read to the next non-white space character.
- Ordinary characters which must match the next input character.
- Control sequences, which have the general format “~*FC”. The character * is an
  optional return suppression character. It provides a method to specify a field which
  is to be omitted. F is the field width of the input field and C determines the type
  of control sequence.

Unless otherwise specified, leading white-space is ignored for all control sequences.
An input field cannot be more than one line wide. The following control sequences
are available:

- A single ~ is expected in the input.
- A decimal integer is expected.
- A floating point number is expected. It must follow the Erlang floating point
  number syntax.
- A string of non-white-space characters is read. If a field width has been
  specified, this number of characters are read and all trailing white-space
  characters are stripped. An Erlang string (list of characters) is returned.
- Similar to a, but the resulting string is converted into an atom.
- The number of characters equal to the field width are read (default is 1) and
  returned as an Erlang string. However, leading and trailing white-space
  characters are not omitted as they are with a. All characters are returned.
- Returns the number of characters which have been scanned up to that point,
  including white-space characters.

It returns:

- ok, InputList] The read was successful and InputList is the list of
  successfully matched and read items.
- {error, What} The read operation failed and the parameter What can be used as
  argument to report_error/1 to produce an error message.
- eof End of file was encountered.

Examples:
> io:fread('enter>', "~f~f~f").
 enter>1.9 35.5e3 15.0
 {ok, [1.90000, 3.55000e+4, 15.0000]}
> io:fread('enter>', "~10f~d").
 enter>  5.67899
 {ok, [5.67800, 99]}
> io:fread('enter>', ":~10s:~10c:").
 enter>: alan : joe :
 {ok, ["alan", "joe "]}

scan_erl_exprs(Prompt)
scan_erl_exprs([IoDevice,] Prompt, StartLine)

Reads data from the standard input (IoDevice), prompting it with Prompt. Reading starts at line number StartLine (1). The data is tokenized as if it were a sequence of Erlang expressions until a final '.' is reached. This token is also returned. It returns:

{ok, Tokens, EndLine} The tokenization succeeded.
{error, ErrorInfo, EndLine} An error occurred.
{eof, EndLine} End of file was encountered.

Example:
> io:scan_erl_exprs('enter>').
 enter>abc(), "hey".
 {ok, [{atom, 1, abc}, {',', 1}, {'}', 1}, {',', 1},
   {string, 1, "hey"}, {dot, 1}], 2}
> io:scan_erl_exprs('enter>').
 enter>1.0er.
 {error, {1, erl_scan, float}, 2}

scan_erl_form(Prompt)
scan_erl_form(IoDevice, Prompt[, StartLine])

Reads data from the standard input (IoDevice), prompting it with Prompt. Starts reading at line number StartLine (1). The data is tokenized as if it were an Erlang form - one of the valid Erlang expressions in an Erlang source file - until a final '.' is reached. This last token is also returned. The return values are the same as for scan_erl_exprs.

parse_erl_exprs(Prompt)
parse_erl_exprs(IoDevice, Prompt[, StartLine])

Reads data from the standard input (IoDevice), prompting it with Prompt. Starts reading at line number StartLine (1). The data is tokenized and parsed as if it were a sequence of Erlang expressions until a final '.' is reached. It returns:

{ok, ExpressionList, EndLine} The parsing was successful.
{error, ErrorInfo, EndLine} An error occurred.
{eof, EndLine} End of file was encountered.

Example:
parse_erl_form(Prompt)
parse_erl_form(IoDevice, Prompt[, StartLine])

Reads data from the standard input (IoDevice), prompting it with Prompt. Starts reading at line number StartLine (1). The data is tokenized and parsed as if it were an Erlang form - one of the valid Erlang expressions in an Erlang source file - until a final '.' is reached. It returns:

{ok, Form, EndLine} The parsing was successful.
{error, ErrorInfo, EndLine} An error occurred.
{eof, EndLine} End of file was encountered.

Standard Input/Output

All Erlang processes have a default standard IO device. This device is used when no IoDevice argument is specified in the IO calls. However, it is sometimes desirable to use an explicit IoDevice argument which refers to the default IO device. This is the case with functions that can access either a file or the default IO device. The atom standard_io has this special meaning. The following example illustrates this:

> io:read('enter>').
enter>foo.
{term, foo}
> io:read(standard_io, 'enter>').
enter>bar.
{term, bar}

There is always a process registered under the name of user. This can be used for sending output to the user.

Error Information

The ErrorInfo mentioned above is the standard ErrorInfo structure which is returned from all IO modules. It has the following format:

{ErrorLine, Module, ErrorDescriptor}

A string which describes the error is obtained with the following call:
apply(Module, format_error, ErrorDescriptor)
io_lib

Erlang Module

This module contains functions for converting to and from strings (lists of characters). They are used for implementing the functions in the io module. There is no guarantee that the character lists returned from some of the functions are flat, they can be deep lists. lists:flatten/1 is used for generating flat lists.

Exports

nl()

Returns a character list which represents a new line character.

write(Term)
write(Term, Depth)

Returns a character list which represents Term. The Depth (-1) argument controls the depth of the structures written. When the specified depth is reached, everything below this level is replaced by "...". For example:

> lists:flatten(io_lib:write({1,[2],[3],[4,5],6,7,8,9})).
"{1,[2],[3],[4,5],6,7,8,9}"
> lists:flatten(io_lib:write({1,[2],[3],[4,5],6,7,8,9}, 5)).
"{1,[2],[3],[4|...],6|...}"

print(Term)
print(Term, Column, LineLength, Depth)

Also returns a list of characters which represents Term, but breaks representations which are longer than one line into many lines and indents each line sensibly. It also tries to detect and output lists of printable characters as strings. Column is the starting column (1), LineLength the maximum line length (80), and Depth the maximum print depth.

fwrite(Format, Data)
format(Format, Data)

Returns a character list which represents Data formatted in accordance with Format. Refer to io [page 159] for a detailed description of the available formatting options. A fault is generated if there is an error in the format string or argument list.

fread(Format, String)
Tries to read String in accordance with the control sequences in Format. Refer to io [page 159] for a detailed description of the available formatting options. It is assumed that String contains whole lines. It returns:

\{ok, InputList, LeftOverChars\} The string was read. InputList is the list of successfully matched and read items, and LeftOverChars are the input characters not used.

\{more, RestFormat, Nchars, InputStack\} The string was read, but more input is needed in order to complete the original format string. RestFormat is the remaining format string, Nchars the number of characters scanned, and InputStack is the reversed list of inputs matched up to that point.

\{error, What\} An error occurred which can be formatted with the call format_error/1.

Example:

> io_lib:fread("~f~f~f", "15.6 17.3e-6 24.5").
\{ok, \[15.6000, 1.73000e-5, 24.5000\], []\}

\textbf{fread(Continuation, CharList, Format)}

This is the re-entrant formatted reader. It returns:

\{done, Result, LeftOverChars\} The input is complete. The result is one of the following:

\{ok, InputList\} The string was read. InputList is the list of successfully matched and read items, and LeftOverChars are the remaining characters.

eof End of file has been encountered. LeftOverChars are the input characters not used.

\{error, What\} An error occurred, which can be formatted with the call format_error/1.

\{more, Continuation\} More data is required to build a term. Continuation must be passed to \texttt{fread/3}, when more data becomes available.

write_atom(Atom)

Returns the list of characters needed to print the atom Atom.

write_string(String)

Returns the list of characters needed to print String as a string.

write_char(Integer)

Returns the list of characters needed to print a character constant.

indentation(String, StartIndent)

Returns the indentation if String has been printed, starting at Indentation.

\textbf{char_list(CharList) \to bool()}

\textbf{STDLIB Reference Manual io_lib 167}
Returns true if CharList is a list of characters, otherwise it returns false.

`deep_char_list(CharList)`
Returns true if CharList is a deep list of characters, otherwise it returns false.

`printable_list(CharList)`
Returns true if CharList is a list of printable characters, otherwise it returns false.

Notes

The module `io_lib` also uses the extra modules `io_lib_format`, `io_lib_fread`, and `io_lib_pretty`. All external interfaces exist in `io_lib`.

Users are strongly advised not to access the other modules directly.

**Note:**
Any undocumented functions in `io_lib` should not be used.

The continuation of the first call to the re-entrant input functions must be []. Refer to Armstrong, Virding, Williams, ‘Concurrent Programming in Erlang’, Chapter 13 for a complete description of how the re-entrant input scheme works.
lib

Erlang Module

The module lib provides the following useful library functions.

Exports

\[ \texttt{flush()} \rightarrow \texttt{void()} \]
Flushes the message buffer of the current process.

\[ \texttt{error_message(Format, Args)} \]
Prints error message Args in accordance with Format in the normal way.

\[ \texttt{progname()} \rightarrow \texttt{atom()} \]
Returns the name of the script that starts the current Erlang session.

\[ \texttt{nonl(List)} \]
Removes the last newline character, if any, in List.

\[ \texttt{send(To, Msg)} \]
This function makes it possible to send a message through apply.

\[ \texttt{sendw(To, Msg)} \]
As send/2, but waits for an answer. It is implemented as follows:
\[
\begin{align*}
\text{sendw(To, Msg)} & \rightarrow \\
& \text{To} ! \{\text{self()}, \text{Msg}\}, \\
& \text{receive} \\
& \quad \text{Reply} \rightarrow \text{Reply} \\
& \text{end}.
\end{align*}
\]
The message returned is not necessarily a reply to the message sent.

Warning

This module is retained for compatibility. It may disappear without warning in a future release.
This module contains functions for list processing. The functions are organized in two groups: those in the first group perform a particular operation on one or several lists, whereas those in the second group perform use a user-defined function (given as the first argument) to perform an operation on one list.

Exports

- `append(ListOfLists) :- List1`
  
  Types:
  - `ListOfLists = [List]`
  - `List = List1 = [term()]`
  
  Returns a list in which all the sub-lists of `ListOfLists` have been appended. For example:
  ```erlang```
  > lists:append([[1, 2, 3], [a, b], [4, 5, 6]]).
  [1, 2, 3, a, b, 4, 5, 6]
  ```erlang```
  
  The result need not be a proper list. The last parameter may be of any datatype and will be the tail in the resulting list. An example:
  ```erlang```
  > lists:append([[a,b],c]).
  [a,b|c]
  ```erlang```
  
  The atom `c` will be the tail of the list and the list is therefore not proper (a proper list ends with []).
  
  As a parameter of `[]` is ignored this example is also valid (although probably useless):
  ```erlang```
  lists:append([],d)).
  ```erlang```

- `append(List1, List2) :- List3`
  
  Types:
  - `List1 = List2 = List3 = [term()]`
  
  Returns a new list `List3` which is made from the elements of `List1` followed by the elements of `List2`. For example:
  ```erlang```
  > lists:append("abc", "def").
  "abcdef"
  ```erlang```
  
  `lists:append(A,B)` is equivalent to `A ++ B`.
  
  The behaviour regarding improper lists is identical to the behaviour of `lists:append/1`
concat(Things) -> string()

Types:
- Things = [Thing]
- Thing = atom() | integer() | float() | string()

Concatenates the ASCII list representation of the elements of Things. The elements of Things can be atoms, integers, floats or strings.

> lists:concat([doc, '/', file, '.', 3]).
"doc/file.3"

delete(Element, List1) -> List2

Types:
- List1 = List2 = [Element]
- Element = term()

Returns a copy of List1, but the first occurrence of Element, if present, is deleted.

duplicate(N, Element) -> List

Types:
- N = int()
- List = [Element]
- Element = term()

Returns a list which contains N copies of the term Element.

Note:
N must be an integer >= 0. For example:

> lists:duplicate(5, xx).
[xx, xx, xx, xx, xx]

flatlength(DeepList) -> int()

Equivalent to length(flatten(DeepList)), but more efficient.

flatten(DeepList) -> List

Types:
- DeepList = [term() | DeepList]

Returns a flattened version of DeepList.

flatten(DeepList, Tail) -> List

Types:
- DeepList = [term() | DeepList]
- Tail = [term()]

Returns a flattened version of DeepList with the tail Tail appended.
keydelete(Key, N, TupleList1) -> TupleList2

Types:
- TupleList1 = TupleList2 = [tuple()]
- N = int()
- Key = term()

Returns a copy of TupleList1 where the first occurrence of a tuple whose Nth element is Key is deleted, if present.

keymember(Key, N, TupleList) -> bool()

Types:
- TupleList = [tuple()]
- N = int()
- Key = term()

Searches the list of tuples TupleList for a tuple whose Nth element is Key.

keymerge(N, List1, List2)

Types:
- N = int()
- List1 = List2 = [tuple()]

Returns the sorted list formed by merging List1 and List2. The merge is performed on the Nth element of each tuple. Both List1 and List2 must be key-sorted prior to evaluating this function; otherwise the order of the elements in the result will be undefined. When elements in the input lists compare equal, elements from List1 are picked before elements from List2.

keyreplace(Key, N, TupleList1, NewTuple) -> TupleList2

Types:
- Key = term()
- N = int()
- TupleList1 = TupleList2 = [tuple()]
- NewTuple = tuple()

Returns a list of tuples. In this list, a tuple is replaced by the tuple NewTuple. This tuple is the first tuple in the list where the element number N is equal to Key.

keysearch(Key, N, TupleList) -> Result

Types:
- TupleList = [tuple()]
- N = int()
- Key = term()
- Result = {value, tuple()} | false

Searches the list of the tuples TupleList for Tuple whose Nth element is Key. Returns {value, Tuple} if such a tuple is found, or false if no such tuple is found.

keysort(N, List1) -> List2
last(List) -> Element

Types:
- List = [Element]
- Element = term()
Returns the last element in List.

max(List) -> Max

Types:
- List = [Element]
- Element = Max = term()
Returns the maximum element of List.

member(Element, List) -> bool()

Types:
- List = [Element]
- Element = term()
Returns true if Element is contained in the list List, otherwise false.

merge(ListOfLists) -> List1

Types:
- ListOfLists = [List]
- List = List1 = [term()]
Returns the sorted list formed by merging all the sub-lists of ListOfLists. All sub-lists must be sorted prior to evaluating this function.

merge(List1, List2) -> List3

Types:
- List1 = List2 = List3 = term()
Returns the sorted list formed by merging List1 and List2. Both List1 and List2 must be sorted prior to evaluating this function.

merge(Fun, List1, List2) -> List

Types:
- List = List1 = List2 = [Element]
- Fun = fun(Element, Element) -> bool()
- Element = term()
Returns the sorted list formed by merging List1 and List2. Both List1 and List2 must be sorted according to the ordering function Fun prior to evaluating this function. Fun(A, B) should return true if A comes before B in the ordering, false otherwise.

merge3(List1, List2, List3) \rightarrow List4

Types:
- List1 = List2 = List3 = List4 = [term()]

Returns the sorted list formed by merging List1, List2 and List3. All of List1, List2 and List3 must be sorted prior to evaluating this function.

min(List) \rightarrow Min

Types:
- List = [Element]
- Element = Max = term()

Returns the minimum element of List.

nth(N, List) \rightarrow Element

Types:
- N = int()
- List = [Element]
- Element = term()

Returns the Nth element of the List. For example:

> lists: nth(3, [a, b, c, d, e]).
c

nthtail(N, List1) \rightarrow List2

Types:
- N = int()
- List1 = List2 = [Alpha]

Returns the Nth tail of List. For example:

> lists: nthtail(3, [a, b, c, d, e]).
[d, e]

prefix(List1, List2) \rightarrow bool()

Types:
- List1 = List2 = [term()]

Returns true if List1 is a prefix of List2, otherwise false.

reverse(List1) \rightarrow List2

Types:
- List1 = List2 = [term()]

Returns a list with the top level elements in List1 in reverse order.
reverse(List1, List2) -> List3

Types:
  • List1 = List2 = List3 = [term()]

Returns a list where List1 has been reversed and appended to the beginning of List2. Equivalent to reverse(List1) ++ List2. For example:

> lists:reverse([1, 2, 3, 4], [a, b, c]).
[4, 3, 2, 1, a, b, c]

seq(From, To) -> [int()]
seq(From, To, Incr) -> [int()]

Types:
  • From = To = Incr = int()

Returns a sequence of integers which starts with From and contains the successive results of adding Incr to the previous element, until To has been reached or passed (in the latter case, To is not an element of the sequence). If To - From has a different sign from Incr, or if Incr = 0 and From is different from To, an error is signalled (this implies that the result is never an empty list - the first element is always From).

seq(From, To) is equivalent to seq(From, To, 1).

Examples:

> lists:seq(1, 10).
[1, 2, 3, 4, 5, 6, 7, 8, 9, 10]

> lists:seq(1, 20, 3).
[1, 4, 7, 10, 13, 16, 19]

> lists:seq(1, 1, 0).
[1]

sort(List1) -> List2

Types:
  • List1 = List2 = [term()]

Returns a list which contains the sorted elements of List1.

sort(Fun, List1) -> List2

Types:
  • List1 = List2 = [Element]
  • Fun = fun(Element, Element) -> bool()
  • Element = term()

Returns a list which contains the sorted elements of List1, according to the ordering function Fun. Fun(A, B) should return true if A comes before B in the ordering, false otherwise.

sublist(List, N) -> List1

Types:
- List1 = List2 = [term()]  
- N = int()

Returns the first N elements of List. It is not an error for N to exceed the length of the list when List is a proper list - in that case the whole list is returned.

sublist(List1, Start, Length) -> List2

Types:
- List1 = List2 = [term()]
- Start = End = int()

Returns the sub-list of List starting at Start of length Length. Terminates with a runtime failure if Start is not in List, but a sub-list of a length less than Length is accepted. Start is considered to be in List if Start >= 1 and Start <= length(List)+1.

subtract(List1, List2) -> List3

Types:
- List1 = List2 = List3 = [term()]

Returns a new list List3 which is a copy of List1, subjected to the following procedure: for each element in List2, its first occurrence in List1 is removed. For example:

```
> lists:subtract("123212", "212").
"312".
```

lists:subtract(A,B) is equivalent to A -- B.

suffix(List1, List2) -> bool()

Returns true if List1 is a suffix of List2, otherwise false.

sum(List) -> number()

Types:
- List = [number()]

Returns the sum of the elements in List.

ukeymerge(N, List1, List2)

Types:
- N = int()
- List1 = List2 = [tuple()]

Returns the sorted list formed by merging List1 and List2 while removing consecutive duplicates. The merge is performed on the Nth element of each tuple. Both List1 and List2 must be key-sorted prior to evaluating this function; otherwise the order of the elements in the result will be undefined. When elements in the input lists compare equal, elements from List1 are picked before elements from List2.

ukeysort(N, List1) -> List2

Types:
STDLIB Reference Manual

- \( N = \text{int}() \)
- \( \text{List1} = \text{List2} = [\text{tuple}] \)

Returns a list containing the sorted elements of \( \text{List1} \) with consecutive duplicates removed. \( \text{TupleList1} \) must be a list of tuples, and the sort is performed on the \( N \)th element of the tuple. The sort is stable.

\textit{umerge(ListOfLists)} \( \rightarrow \) \( \text{List1} \)

Types:
- \( \text{ListOfLists} = [\text{List}] \)
- \( \text{List} = \text{List1} = [\text{term}] \)

Returns the sorted list formed by merging all the sub-lists of \( \text{ListOfLists} \) while removing duplicates. All sub-lists must be sorted and contain no duplicates prior to evaluating this function.

\textit{umerge(List1, List2)} \( \rightarrow \) \( \text{List3} \)

Types:
- \( \text{List1} = \text{List2} = \text{List3} = [\text{term}] \)

Returns the sorted list formed by merging \( \text{List1} \) and \( \text{List2} \) while removing duplicates. Both \( \text{List1} \) and \( \text{List2} \) must be sorted and contain no duplicates prior to evaluating this function.

\textit{umerge(Fun, List1, List2)} \( \rightarrow \) \( \text{List} \)

Types:
- \( \text{List} = \text{List1} = \text{List2} = [\text{Element}] \)
- \( \text{Fun} = \text{fun}(\text{Element}, \text{Element}) \rightarrow \text{bool}() \)
- \( \text{Element} = \text{term}() \)

Returns the sorted list formed by merging \( \text{List1} \) and \( \text{List2} \) while removing consecutive duplicates. Both \( \text{List1} \) and \( \text{List2} \) must be sorted according to the ordering function \( \text{Fun} \) prior to evaluating this function. \( \text{Fun}(A, B) \) should return \( \text{true} \) if \( A \) comes before \( B \) in the ordering, \( \text{false} \) otherwise.

\textit{umerge3(List1, List2, List3)} \( \rightarrow \) \( \text{List4} \)

Types:
- \( \text{List1} = \text{List2} = \text{List3} = \text{List4} = [\text{term}] \)

Returns the sorted list formed by merging \( \text{List1}, \text{List2} \) and \( \text{List3} \) while removing duplicates. All of \( \text{List1}, \text{List2} \) and \( \text{List3} \) must be sorted and contain no duplicates prior to evaluating this function.

\textit{usort(List1)} \( \rightarrow \) \( \text{List2} \)

Types:
- \( \text{List1} = \text{List2} = [\text{term}] \)

Returns a list which contains the sorted elements of \( \text{List1} \) without duplicates.

\textit{usort(Fun, List1)} \( \rightarrow \) \( \text{List2} \)
Types:
- List1 = List2 = [Element]
- Fun = fun(Element, Element) -> bool()
- Element = term()

Returns a list which contains the sorted elements of List1 with consecutive duplicates removed, according to the ordering function Fun. Fun(A, B) should return true if A comes before B in the ordering, false otherwise.

all(Pred, List) -> bool()

Types:
- Pred = fun(A) -> bool()
- List = [A]

Returns true if all elements X in List satisfy Pred(X).

any(Pred, List) -> bool()

Types:
- Pred = fun(Element) -> bool()
- List = [Element]
- Element = term()

Returns true if any of the elements in List satisfies Pred.

dropwhile(Pred, List1) -> List2

Types:
- Pred = fun(A) -> bool()
- List1 = List2 = [A]

Drops elements X from List1 while Pred(X) is true and returns the remaining list.

filter(Pred, List1) -> List2

Types:
- Pred = fun(A) -> bool()
- List1 = List2 = [A]

List2 is a list of all elements X in List1 for which Pred(X) is true.

flatMap(Function, List1) -> Element

Types:
- Function = fun(A) -> B
- List1 = [A]
- Element = [B]

flatMap behaves as if it had been defined as follows:

flatMap(Func, List) ->
  append(map(Func, List))

foldl(Function, Acc0, List) -> Acc1
Types:
- Function = fun(A, AccIn) -> AccOut
- List = [A]
- Acc0 = Acc1 = AccIn = AccOut = term()

Acc0 is returned if the list is empty. For example:

> lists:foldl(fun(X, Sum) -> X + Sum end, 0, [1,2,3,4,5]).
15
> lists:foldl(fun(X, Prod) -> X * Prod end, 1, [1,2,3,4,5]).
120

foldr(Function, Acc0, List) -> Acc1

Types:
- Function = fun(A, AccIn) -> AccOut
- List = [A]
- Acc0 = Acc1 = AccIn = AccOut = term()

Calls Function on successive elements of List together with an extra argument Acc (short for accumulator). Function must return a new accumulator which is passed to the next call. Acc0 is returned if the list is empty. foldr differs from foldl in that the list is traversed “bottom up” instead of “top down”. foldl is tail recursive and would usually be preferred to foldr.

foreach(Function, List) -> void()

Types:
- Function = fun(A) -> void()
- List = [A]

Applies the function Function to each of the elements in List. This function is used for its side effects and the evaluation order is defined to be the same as the order of the elements in the list.

map(Func, List1) -> List2

Types:
- Func = fun(A) -> B
- List1 = [A]
- List2 = [B]

map takes a function from As to Bs, and a list of As and produces a list of Bs by applying the function to every element in the list. This function is used to obtain the return values. The evaluation order is implementation dependent.

mapfoldl(Function, Acc0, List1) -> {List2, Acc}

Types:
- Function = fun(A, AccIn) -> {B, AccOut}
- Acc0 = Acc1 = AccIn = AccOut = term()
- List1 = [A]
- List2 = [B]

foreach(Function, List) -> void()
mapfold combines the operations of map and foldl into one pass. For example, we could sum the elements in a list and double them at the same time:

```erlang
> lists:mapfoldl(fun(X, Sum) -> {2*X, X+Sum} end, 0, [1,2,3,4,5]).
{[2,4,6,8,10],15}
```

mapfoldr(Function, Acc0, List1) - {List2, Acc}

Types:
- Function = fun(A, AccIn) -> {B, AccOut}
- Acc0 = Acc1 = AccIn = AccOut = term()
- List1 = [A]
- List2 = [B]

mapfold combines the operations of map and foldr into one pass.

splitwith(Pred, List) - {List1, List2}

Types:
- Pred = fun(A) -> bool()
- List = List1 = List2 = [A]

Partitions Lists into List1 and List2 according to Pred.

splitwith behaves as if it had been defined as follows:

```erlang
splitwidth(Pred, List) ->
  {takewhile(Pred, List), dropwhile(Pred, List)}.
```

Note also that List == List1 ++ List2.

takewhile(Pred, List1) - List2

Types:
- Pred = fun(A) -> bool()
- List1 = List2 = [A]

Returns the longest prefix of List1 for which all elements X in List1 satisfy Pred(X).

Relics

Some of the exported functions in lists.erl are not documented. In particular, this applies to a number of maps and folds which have an extra argument for environment passing. These functions are no longer needed because Erlang 4.4 and later releases have Funs.

**Note:**

Any undocumented functions in lists should not be used.
log_mf_h

Erlang Module

The log_mf_h is a gen_event handler module which can be installed in any gen_event process. It logs onto disk all events which are sent to an event manager. Each event is written as a binary which makes the logging very fast. However, a tool such as the Report Browser (rb) must be used in order to read the files. The events are written to multiple files. When all files have been used, the first one is re-used and overwritten. The directory location, the number of files, and the size of each file are configurable. The directory will include one file called index, and report files 1, 2, ......

Exports

init(Dir, MaxBytes, MaxFiles)
init(Dir, MaxBytes, MaxFiles, Pred) -> Args

Types:
- Dir = string()
- MaxBytes = integer()
- MaxFiles = 0 < integer() < 256
- Pred = fun(Event) -> boolean()
- Event = term()
- Args = args()

Initiates the event handler. This function returns Args, which should be used in a call to gen_event:add_handler(EventMgr, log_mf_h, Args).

Dir specifies which directory to use for the log files. MaxBytes specifies the size of each individual file. MaxFiles specifies how many files are used. Pred is a predicate function used to filter the events. If no predicate function is specified, all events are logged.

See Also

gen_event(3), rb(3)
This module provides an interface to a number of mathematical functions.

Exports

pi() -> float()
   A useful number.

sin(X)

exp(X)

log(X)

log10(X)

pow(X, Y)

sqrt(X)

erf(X) -> float()

Types:
   • X = Y = number()
   A collection of math functions which return floats. Arguments are numbers.

Returns the error function of X, where

   erf(X) = 2/sqrt(pi)*integral from 0 to X of exp(-t*t) dt.
erfc(X) -> float()

Types:
• X = number()

erfc(X) returns 1.0 - erf(X), computed by methods that avoid cancellation for large X.

Bugs

As these are the C library, the bugs are the same.
orddict

Erlang Module

orddict implements a Key - Value dictionary. An orddict is a representation of a dictionary, where a list of pairs is used to store the keys and values. The list is ordered after the keys.

This module provides exactly the same interface as the module dict but with a defined representation.
Sets are collections of elements with no duplicate elements. An ordset is a representation of a set, where an ordered list is used to store the elements of the set. An ordered list is more efficient than an unordered list.

This module provides exactly the same interface as the module sets but with a defined representation.
This (experimental) module implements process groups. A process group is a group of processes that can be accessed by a common name. For example, a group named `foobar` can include a set of processes as members of this group and they can be located on different nodes.

When messages are sent to the named group, all members of the group receive the message. The messages are serialized. If the process `P1` sends the message `M1` to the group, and process `P2` simultaneously sends message `M2`, then all members of the group receive the two messages in the same order. If members of a group terminate, they are automatically removed from the group.

This module is not complete. The module is inspired by the ISIS system and the causal order protocol of the ISIS system should also be implemented. At the moment, all messages are serialized by sending them through a group master process.

**Exports**

- `create(PgName)`  
  Creates an empty group named `PgName` on the current node.

- `create(PgName, Node)`  
  Creates an empty group on the node `Node`.

- `join(PgName, Pid)`  
  Joins the Pid `Pid` to the process group `PgName`.

- `send(PgName, Message)`  
  Sends the tuple `{pg_message, From, PgName, Message}` to all members of the process group.

- `esend(PgName, Mess)`  
  Sends the tuple `{pg_message, From, PgName, Message}` to all members of the process group, except the current node.

- `members(PgName)`  
  Returns a list of the current members in the process group.
pool

Erlang Module

pool can be used to run a set of Erlang nodes as a pool of computational processors. It is organized as a master and a set of slave nodes and includes the following features:

- The slave nodes send regular reports to the master about their current load.
- Queries can be sent to the master to determine which node will have the least load.

The BIF statistics(run_queue) is used for estimating future loads. It returns the length of the queue of ready to run processes in the Erlang runtime system.

The slave nodes are started with the slave module. This effects, tty IO, file IO, and code loading.

If the master node fails, the entire pool will exit.

Exports

start(Name)

Starts a new pool. The file .hosts.erlang is read to find host names where the pool nodes can be started. The current working directory is searched first, then the home directory, and finally the root directory of the Erlang runtime system. The start-up procedure fails if the file is not found.

Name is sent to all pool nodes. This is used as the first part of the node name in the alive/3 statements for the nodes.

The function net_ads:host_file() reads the file .hosts.erlang for host names. The slave nodes are started with slave:start. See slave(3).

start/1 is synchronous and all the nodes, as well as all the system servers, are running when it returns a value. Access rights must also be set so that all nodes in the pool have the authority to access each other.

start(Name, Args)

This function is the same as start/1, except that the environment Args is passed to the pool nodes. See slave(3).

attach(Node)

This function ensures that a pool master is running and includes Node in the pool master’s pool of nodes.

stop()
Pool STDLIB Reference Manual

Stops the pool and kills all the slave nodes.

get_nodes()
Returns a list of the current member nodes of the pool.

pspawn(Mod, Fun, Args)
Spawns a process on the pool node which is expected to have the lowest future load.

pspawn_link(Mod, Fun, Args)
Spawn links a process on the pool node which is expected to have the lowest future load.

get_node()
Returns the node ID of the node with the expected lowest future load.

new_node(Host, Name)
Starts a new node and attaches it to an already existing pool. If there is no existing pool, it starts a pool with two nodes, the current node and `Node`. This function can also be used as a convenient way of starting new nodes, even if the load distribution facilities of `pool` are of no interest.

Files

`$HOME/.hosts.erlang` is used to pick hosts where nodes can be started.
`$HOME/erlang.slave.out.HOST` is used for all additional IO that may come from the slave nodes on standard IO. If the start-up procedure does not work, this file may indicate the reason.
The `proc_lib` module is used to initialize some useful information when a process starts. The registered names, or the process identities, of the parent process, and the parent ancestors, are stored together with information about the function initially called in the process.

A crash report is generated if the process terminates with a reason other than normal or shutdown. shutdown is used to terminate an abnormal process in a controlled manner. A crash report contains the previously stored information such as ancestors and initial function, the termination reason, and information regarding other processes which terminate as a result of this process terminating.

The crash report is sent to the error_logger. An event handler has to be installed in the error_logger event manager in order to handle these reports. The crash report is tagged crash_report and the format/1 function should be called in order to format the report.

**Exports**

```
spawn(Module,Func,Args) -> Pid
spawn(Node,Module,Func,Args) -> Pid
```

Types:
- Module = atom()
- Func = atom()
- Args = [Arg]
- Arg = term()
- Node = atom()
- Pid = pid()

Spawns a new process and initializes it as described above. The process is spawned using the spawn BIF. The process can be spawned on another Node.

```
spawn_link(Module,Func,Args) -> Pid
spawn_link(Node,Module,Func,Args) -> Pid
```

Types:
- Module = atom()
- Func = atom()
- Args = [Arg]
- Arg = term()
- Node = atom()
• Pid = pid()

Spawns a new process and initializes it as described above. The process is spawned using the spawn_link BIF. The process can be spawned on another Node.

\[
\text{start(Module, Func, Args)} \rightarrow \text{Ret}
\]

\[
\text{start(Module, Func, Args, Time)} \rightarrow \text{Ret}
\]

\[
\text{start_link(Module, Func, Args)} \rightarrow \text{Ret}
\]

\[
\text{start_link(Module, Func, Args, Time)} \rightarrow \text{Ret}
\]

Types:
• Module = atom()
• Func = atom()
• Args = [Arg]
• Arg = term()
• Time = integer \geq 0 \mid \infty
• Ret = term() \mid \text{error, Reason}

Starts a new process synchronously. Spawns the process using proc_lib:spawn/3 or proc_lib:spawn_link/3, and waits for the process to start. When the process has started, it must call proc_lib:init_ack(Parent, Ret) or proc_lib:init_ack(Ret), where Parent is the process that evaluates start. At this time, Ret is returned from start.

If the start_link function is used and the process crashes before proc_lib:init_ack is called, \{error, Reason\} is returned if the calling process traps exits.

If Time is specified as an integer, this function waits for Time milliseconds for the process to start (proc_lib:init_ack). If it has not started within this time, \{error, timeout\} is returned, and the process is killed.

\[
\text{init_ack(Parent, Ret)} \rightarrow \text{void()}
\]

\[
\text{init_ack(Ret)} \rightarrow \text{void()}
\]

Types:
• Parent = pid()
• Ret = term()

This function is used by a process that has been started by a proc_lib:start function. It tells Parent that the process has initialized itself, has started, or has failed to initialize itself. The init_ack/1 function uses the parent value previously stored by the proc_lib:start function. If the init_ack function is not called (e.g. if the init function crashes) and proc_lib:start/3 is used, that function never returns and the parent hangs forever. This can be avoided by using a time out in the call to start, or by using start_link.

The following example illustrates how this function and proc_lib:start_link are used.
-module(my_proc).
-export([start_link/0]).

start_link() ->
    proc_lib:start_link(my_proc, init, [self()]).

init(Parent) ->
    case do_initialization() of
    ok ->
        proc_lib:init_ack(Parent, {ok, self()});
    {error, Reason} ->
        exit(Reason)
    end,
    loop().

loop() ->
    receive
    ....

format(CrashReport) ->
    string()

Types:
- CrashReport = void()

Formats a previously generated crash report. The formatted report is returned as a string.

initial_call(PidOrPinfo) ->
    {Module,Function,Args} | false

Types:
- PidOrPinfo = pid() | {X,Y,Z} | ProcInfo
- X = Y = Z = int()
- ProcInfo = [void()]
- Module = atom()
- Function = atom()
- Args = [term()]

Extracts the initial call of a process that was spawned using the spawn functions described above. PidOrPinfo can either be a Pid, an integer tuple (from which a pid can be created), or the process information of a process (fetched through a erlang:process_info/1 function call).

translate_initial_call(PidOrPinfo) ->
    {Module,Function,Arity}

Types:
- PidOrPinfo = pid() | {X,Y,Z} | ProcInfo
- X = Y = Z = int()
- ProcInfo = [void()]
- Module = atom()
- Function = atom()
- Arity = int()
Extracts the initial call of a process which was spawned using the spawn functions described above. If the initial call is to one of the system defined behaviours such as gen_server or gen_event, it is translated to more useful information. If a gen_server is spawned, the returned Module is the name of the callback module and Function is init (the function that initiates the new server).

A supervisor and a supervisor_bridge are also gen_server processes. In order to return information that this process is a supervisor and the name of the call-back module, Module is supervisor and Function is the name of the supervisor callback module. Arity is 1 since the init/1 function is called initially in the callback module.

By default, \{proc_lib,init,p,5\} is returned if no information about the initial call can be found. It is assumed that the caller knows that the process has been spawned with the proc_lib module.

PidOrPinfo can either be a Pid, an integer tuple (from which a pid can be created), or the process information of a process (fetched through a erlang:process_info/1 function call).

This function is used by the c:I/0 and c:regs/0 functions in order to present process information.

See Also

error_logger(3)
queue

Erlang Module

This module implements FIFO queues in an efficient manner.

Exports

new() -> Queue

Types:
- Queue = queue()

Returns an empty queue.

in(Item, Q1) -> Q2

Types:
- Item = term()
- Q1 = Q2 = queue()

Inserts Item into the queue Q1. Returns a new queue Q2.

out(Q) -> Result

Types:
- Result = [{value, Item}, Q1] | {empty, Q1}
- Q = Q1 = queue()

Removes the oldest element from the queue Q. Returns the tuple {value, Item}, Q1, where Item is the element removed and Q1 is an identifier for the new queue. If Q is empty, the tuple {empty, Q} is returned.

to_list(Q) -> list()

Types:
- Q = queue()

Returns a list of the elements in the queue, with the oldest element first.
random

Erlang Module

Random number generator. The method is attributed to B.A. Wichmann and I.D. Hill,
in 'An efficient and portable pseudo-random number generator', Journal of Applied
The current algorithm is a modification of the version attributed to Richard A O’Keefe
in the standard Prolog library.
Every time a random number is requested, a state is used to calculate it, and a new state
produced. The state can either be implicit (kept in the process dictionary) or be an
explicit argument and return value. In this implementation, the state (the type ran())
consists of a tuple of three integers.

Exports

seed() -> ran()
Seeds random number generation with default (fixed) values in the process dictionary,
and returns the old state.

seed(A1, A2, A3) -> ran()
Types:
• A1 = A2 = A3 = int()
Seeds random number generation with integer values in the process dictionary, and
returns the old state.

seed0() -> ran()
Returns the default state.

uniform() -> float()
Returns a random float uniformly distributed between 0.0 and 1.0, updating the state
in the process dictionary.

uniform(N) -> int()
Types:
• N = int()
Given an integer N >= 1, uniform/1 returns a random integer uniformly distributed
between 1 and N, updating the state in the process dictionary.
uniform_s(State0) -> {float(), State1}

Types:
- State0 = State1 = ran()

Given a state, uniform_s/1 returns a random float uniformly distributed between 0.0 and 1.0, and a new state.

uniform_s(N, State0) -> {int(), State1}

Types:
- N = int()
- State0 = State1 = ran()

Given an integer \( N \geq 1 \) and a state, uniform_s/2 returns a random integer uniformly distributed between 1 and \( N \), and a new state.

Note

Some of the functions use the process dictionary variable random_seed to remember the current seed.

If a process calls uniform/0 or uniform/1 without setting a seed first, seed/0 is called automatically.
This module contains functions for regular expression matching and substitution.

Exports

match(String, RegExp) -> MatchRes

Types:
- String = RegExp = string()
- MatchRes = {match,Start,Length} | nomatch | {error,errordesc()}
- Start = Length = integer()

Finds the first, longest match of the regular expression RegExp in String. This function searches for the longest possible match and returns the first one found if there are several expressions of the same length. It returns as follows:

- {match,Start,Length} if the match succeeded. Start is the starting position of the match, and Length is the length of the matching string.
- nomatch if there were no matching characters.
- {error,Error} if there was an error in RegExp.

first_match(String, RegExp) -> MatchRes

Types:
- String = RegExp = string()
- MatchRes = {match,Start,Length} | nomatch | {error,errordesc()}
- Start = Length = integer()

Finds the first match of the regular expression RegExp in String. This call is usually faster than match and it is also a useful way to ascertain that a match exists. It returns as follows:

- {match,Start,Length} if the match succeeded. Start is the starting position of the match and Length is the length of the matching string.
- nomatch if there were no matching characters.
- {error,Error} if there was an error in RegExp.

matches(String, RegExp) -> MatchRes

Types:
- String = RegExp = string()
- **MatchRes = (match, Matches) | {error, errordesc()}**
- **Matches = list()**  

Finds all non-overlapping matches of the expression *RegExp* in *String*. It returns as follows:

- *(match, Matches)* if the regular expression was correct. The list will be empty if there was no match. Each element in the list looks like *(Start, Length)*, where *Start* is the starting position of the match, and *Length* is the length of the matching string.
- *(error, Error)* if there was an error in *RegExp*.

### sub(*String*, *RegExp*, *New*) → *SubRes*

**Types:**
- **String** = *RegExp* = *New* = string
- **SubRes** = *(ok, NewString, RepCount) | {error, errordesc()}*
- **RepCount** = integer

Substitutes the first occurrence of a substring matching *RegExp* in *String* with the string *New*. A & in the string *New* is replaced by the matched substring of *String*. \& puts a literal & into the replacement string. It returns as follows:

- *(ok, NewString, RepCount)* if *RegExp* is correct. *RepCount* is the number of replacements which have been made (this will be either 0 or 1).
- *(error, Error)* if there is an error in *RegExp*.

### gsub(*String*, *RegExp*, *New*) → *SubRes*

**Types:**
- **String** = *RegExp* = *New* = string
- **SubRes** = *(ok, NewString, RepCount) | {error, errordesc()}*
- **RepCount** = integer

The same as *sub*, except that all non-overlapping occurrences of a substring matching *RegExp* in *String* are replaced by the string *New*. It returns:

- *(ok, NewString, RepCount)* if *RegExp* is correct. *RepCount* is the number of replacements which have been made.
- *(error, Error)* if there is an error in *RegExp*.

### split(*String*, *RegExp*) → *SplitRes*

**Types:**
- **String** = *RegExp* = string
- **SubRes** = *(ok, FieldList) | {error, errordesc()}*
- **FieldList** = [string()]

*String* is split into fields (sub-strings) by the regular expression *RegExp*. If the separator expression is " " (a single space), then the fields are separated by blanks and/or tabs and leading and trailing blanks and tabs are discarded. For all other values of the separator, leading and trailing blanks and tabs are not discarded. It returns:
{ok, FieldList} to indicate that the string has been split up into the fields of FieldList.
{error, Error} if there is an error in RegExp.

```
sh_to_awk(ShRegExp) -> AwkRegExp
Types:
• ShRegExp AwkRegExp = string()
• SubRes = {ok, NewString, RepCount} | {error, errordesc()}
• RepCount = integer()
```

Converts the sh type regular expression ShRegExp into a full AWK regular expression. Returns the converted regular expression string. Sh expressions are used in the shell for matching file names and have the following special characters:

* matches any string including the null string.
? matches any single character.
[..] matches any of the enclosed characters. Character ranges are specified by a pair of characters separated by a -. If the first character after [ is a !, then any character not enclosed is matched.

It may sometimes be more practical to use sh type expansions as they are simpler and easier to use, even though they are not as powerful.

```
parse(RegExp) -> ParseRes
Types:
• RegExp = string()
• ParseRes = {ok, RE} | {error, errordesc()}
```

Parses the regular expression RegExp and builds the internal representation used in the other regular expression functions. Such representations can be used in all of the other functions instead of a regular expression string. This is more efficient when the same regular expression is used in many strings. It returns:

{ok, RE} if RegExp is correct and RE is the internal representation.
{error, Error} if there is an error in RegExpString.

```
format_error(ErrorDescriptor) -> string()
Types:
• ErrorDescriptor = errordesc()
```

Returns a string which describes the error ErrorDescriptor returned when there is an error in a regular expression.
Regular Expressions

The regular expressions allowed here is a subset of the set found in egrep and in the AWK programming language, as defined in the book, The AWK Programming Language, by A. V. Aho, B. W. Kernighan, P. J. Weinberger. They are composed of the following characters:

c matches the non-metacharacter c.
\c matches the escape sequence or literal character c.
. matches any character.
^ matches the beginning of a string.
$ matches the end of a string.
[abc...] character class, which matches any of the characters abc... Character ranges are specified by a pair of characters separated by a -.
[^abc...] negated character class, which matches any character except abc....
r1 | r2 alternation. It matches either r1 or r2.
r1r2 concatenation. It matches r1 and then r2.
r+ matches one or more rs.
r* matches zero or more rs.
r? matches zero or one rs.
(r) grouping. It matches r.

The escape sequences allowed are the same as for Erlang strings:
\b backspace
\f form feed
\n newline (line feed)
\r carriage return
\t tab
\e escape
\v vertical tab
\s space
\d delete
\ddd the octal value ddd
\c any other character literally, for example \ for backslash, \" for ")

To make these functions easier to use, in combination with the function io:get_line which terminates the input line with a new line, the $ characters also matches a string ending with "...
". The following examples define Erlang data types:

Atoms    [a-z][0-9a-zA-Z]*

Variables [A-Z][0-9a-zA-Z]*

Regular expressions are written as Erlang strings when used with the functions in this module. This means that any \ or " characters in a regular expression string must be written with \ as they are also escape characters for the string. For example, the regular expression string for Erlang floats is:

```
"(\+|-)?[0-9]+\.[0-9]+((E|e)(\+|-)?[0-9]+)?"
```

It is not really necessary to have the escape sequences as part of the regular expression syntax as they can always be generated directly in the string. They are included for completeness and can also be useful when generating regular expressions, or when they are entered other than with Erlang strings.
Sets are collections of elements with no duplicate elements. The representation of a set is not defined.

Exports

new() -> Set
Types:
  • Set = set()
Returns a new empty ordered set.

is_set(Set) -> bool()
Types:
  • Set = term()
Returns true if Set is an ordered set of elements, otherwise false.

size(Set) -> int()
Types:
  • Set = term()
Returns the number of elements in Set.

to_list(Set) -> List
Types:
  • Set = set()
  • List = [term()]
Returns the elements of Set as a list.

from_list(List) -> Set
Types:
  • List = [term()]
  • Set = set()
Returns an ordered set of the elements in List.

is_element(Element, Set) -> bool()
Sets

Returns true if Element is an element of Set, otherwise false.

```prolog
add_element(Element, Set1) -> Set2
```

Returns a new ordered set formed from Set1 with Element inserted.

```prolog
del_element(Element, Set1) -> Set2
```

Returns Set1, but with Element removed.

```prolog
union(Set1, Set2) -> Set3
```

Returns the merged (union) set of Set1 and Set2.

```prolog
union(SetList) -> Set
```

Returns the merged (union) set of the list of sets.

```prolog
intersection(Set1, Set2) -> Set3
```

Returns the intersection of Set1 and Set2.

```prolog
intersection(SetList) -> Set
```

Returns the intersection of the non-empty list of sets.

```prolog
subtract(Set1, Set2) -> Set3
```

Returns the difference of Set1 and Set2.
Returns only the elements of Set1 which are not also elements of Set2.

\[
is\_\text{subset}(\text{Set1}, \text{Set2}) \rightarrow \text{bool}()
\]

Types:
- Set1 = Set2 = set()

Returns true when every element of Set1 is also a member of Set2, otherwise false.

\[
fold(\text{Function}, \text{Acc0}, \text{Set}) \rightarrow \text{Acc1}
\]

Types:
- Function = fun (E, AccIn) -> AccOut
- Acc0 = Acc1 = AccIn = AccOut = term()
- Set = set()

Fold Function over every element in Set returning the final value of the accumulator.

\[
filter(\text{Pred}, \text{Set1}) \rightarrow \text{Set2}
\]

Types:
- Pred = fun (E) -> bool()
- Set1 = Set2 = set()

Filter elements in Set1 with boolean function Fun.
The module shell implements an Erlang shell. The shell is a user interface program for entering expression sequences. The expressions are evaluated and a value is returned. A history mechanism saves previous commands and their values, which can then be incorporated in later commands. How many commands and results to save can be determined by the user, either interactively, by calling `shell:history/1` and `shell:results/1`, or by setting the application configuration parameters `shell_history_length` and `shell_saved_results` for the application stdlib.

Variable bindings, and local process dictionary changes which are generated in user expressions, are preserved and the variables can be used in later commands to access their values. The bindings can also be forgotten so the variables can be re-used.

The special shell commands all have the syntax of (local) function calls. They are evaluated as normal function calls and many commands can be used in one expression sequence.

If a command (local function call) is not recognized by the shell, an attempt is first made to find the function in the module `user_default`, where customized local commands can be placed. If found, then the function is evaluated. Otherwise, an attempt is made to evaluate the function in the module `shell_default`. The module `user_default` must be explicitly loaded.

The shell also permits the user to start multiple concurrent jobs. A job can be regarded as a set of processes which can communicate with the shell.

The shell runs in two modes:

- Normal mode, in which commands can be edited and expressions evaluated
- Job Control Mode JCL, in which jobs can be started, killed, detached and connected.

Only the currently connected job can 'talk' to the shell.
Shell Commands

b() Prints the current variable bindings.
f() Removes all variable bindings.
f(X) Removes the binding of variable X.
h() Prints the history list.

history(N) Sets the number of previous commands to keep in the history list to N. The previous number is returned. The default number is 20.

results(N) Sets the number of results from previous commands to keep in the history list to N. The previous number is returned. The default number is 20.
e(N) Repeats the command N, if N is positive. If it is negative, the ith previous command is repeated (i.e., e(-1) repeats the previous command).
v(N) Uses the return value of the command N in the current command.

help() Evaluates shell:default:help().
c(File) Evaluates shell:default:c(File). This compiles and loads code in File and purges old versions of code, if necessary. Assumes that the file and module names are the same.

Example

The following example is a long dialogue with the shell. Commands starting with > are inputs to the shell. All other lines are output from the shell. All commands in this example are explained at the end of the dialogue.

```
strider 1> erl
Erlang (BEAM) emulator version 4.9

Eshell V4.9 (abort with ^G)
1> Str = "abcd".
"abcd"
2> L = length(Str).
4
3> Descriptor = {L, list_to_atom(Str)}.
{4,abcd}
4> L.
4
5> b().
Descriptor = {4,abcd}
L = 4
Str = "abcd"
ok
6> f(L).
ok
7> b().
Descriptor = {4,abcd}
Str = "abcd"
ok
8> f(L).
ok
```
9> \{L, _\} = Descriptor.
\{4,abcd\}
10> L.
4
11> \{P, Q, R\} = Descriptor.
** exited: \{{badmatch,\{4,abcd\}\},\{erl\_eval,expr,3\}\} **
12> P.
** exited: \{{unbound,\'P\'},\{erl\_eval,expr,3\}\} **
13> Descriptor.
\{4,abcd\}
14> \{P, Q\} = Descriptor.
\{4,abcd\}
15> P.
4
16> f().
oke
17> put(aa, hello). undefined
18> get(aa).
hello
19> Y = test1:demo(1).
11
20> get().
[[aa,worked]]
21> put(aa, hello).
worked
22> Z = test1:demo(2).
** exited: \{{badmatch,1},\{test1,demo,[2]\}\} **
23> Z.
** exited: \{{unbound,\'Z\'},\{erl\_eval,expr,3\}\} **
24> get(aa).
hello
25> erase(), put(aa, hello). undefined
26> spawn(test1, demo, [1]). <0.25.0> 
27> get(aa).
hello
28> io:format("hello hello\n").
hello hello
ok
29> e(28).
hello hello
ok
30> v(28).
ok
31> test1:loop(0).
Hello Number: 0
Hello Number: 1
Hello Number: 2
Hello Number: 3

User switch command
  --> i
  --> c

Hello Number: 3374
Hello Number: 3375
Hello Number: 3376
Hello Number: 3377
Hello Number: 3378
** exited: killed **
32> halt()
strider 2>

Comments

Command 1 sets the variable Str to the string "abcd".
Command 2 sets L to the length of the string evaluating the BIF atom_to_list.
Command 3 builds the tuple Descriptor.
Command 4 prints the value of the variable L.
Command 5 evaluates the internal shell command b(), which is an abbreviation of "bindings". This prints the current shell variables and their bindings. The ok at the end is the return value of the b() function.
Command 6 f(L) evaluates the internal shell command f(L) (abbreviation of "forget"). The value of the variable L is removed.
Command 7 prints the new bindings.
Command 8 shows that the value of L has disappeared from the bindings.
Command 9 performs a pattern matching operation on Descriptor, binding a new value to L.
Command 10 prints the current value of L.
Command 11 tries to match {P, Q, R} against Descriptor which is {4, abc}. The match fails and none of the new variables become bound. The printout starting with "** exited:" is not the value of the expression (the expression had no value because its evaluation failed), but rather a warning printed by the system to inform the user that an error has occurred. The values of the other variables (L, Str, etc.) are unchanged.
Commands 12 and 13 show that P is unbound because the previous command failed, and that Descriptor has not changed.
Commands 14 and 15 show a correct match where P and Q are bound.
Command 16 clears all bindings
The next few commands assume that test1:demo(X) is defined in the following way:
demo(X) ->
put(aa, worked),
X = 1,
X + 10.

Commands 17 and 18 set and inspect the value of the item aa in the process dictionary. Command 19 evaluates test1:demo(1). The evaluation succeeds and the changes made in the process dictionary become visible to the shell. The new value of the dictionary item aa can be seen in command 20.

Commands 21 and 22 change the value of the dictionary item aa to hello and call test1:demo(2). Evaluation fails and the changes made to the dictionary in test1:demo(2), before the error occurred, are discarded.

Commands 23 and 24 show that z was not bound and that the dictionary item aa has retained its original value.

Commands 25, 26 and 27 show the effect of evaluating test1:demo(1) in the background. In this case, the expression is evaluated in a newly spawned process. Any changes made in the process dictionary are local to the newly spawned process and therefore not visible to the shell.

Commands 28, 29 and 30 use the history facilities of the shell.

Command 29 is e(28). This re-evaluates command 28. Command 30 is v(28). This uses the value (result) of command 28. In the cases of a pure function (a function with no side effects), the result is the same. For a function with side effects, the result can be different.

For the next command, it is assumed that test1:loop(N) is defined in the following way:

loop(N) ->
io:format("Hello Number: ~w~n", [N]),
    loop(N+1).

Command 31 evaluates test1:loop(0), which puts the system into an infinite loop. At this point the user types Control G, which suspends output from the current process, which is stuck in a loop, and activates JCL mode. In JCL mode the user can start and stop jobs.

In this particular case, the i command ("interrupt") is used to terminate the looping program, and the c command is used to connect to the shell again. Since the process was running in the background before we killed it, there will be more printouts before the "** exited: killed **" message is shown.

The halt() command exits the Erlang runtime system.
JCL Mode

When the shell starts, it starts a single evaluator process. This process, together with any local processes which it spawns, is referred to as a job. Only the current job, which is said to be connected, can perform operations with standard IO. All other jobs, which are said to be detached, are blocked if they attempt to use standard IO.

All jobs which do not use standard IO run in the normal way.

‘^G (Control G) detaches the current job and JCL mode is activated. The JCL mode prompt is "-->". If "?" is entered at the prompt, the following help message is displayed:

```
-->?
c [nn] - connect to job
i [nn] - interrupt job
k [nn] - kill job
j - list all jobs
s - start local shell
r [node] - start remote shell
q - quit Erlang
? | h - this message
```

The JCL commands have the following meaning:

- **c [nn]** Connects to job number <nn> or the current job. The standard shell is resumed. Operations which use standard IO by the current job will be interleaved with user inputs to the shell.
- **i [nn]** Stops the current evaluator process for job number <nn> or the current job, but does not kill the shell process. Accordingly, any variable bindings and the process dictionary will be preserved and the job can be connected again. This command can be used to interrupt an endless loop.
- **k [nn]** Kills job number <nn> or the current job. All spawned processes in the job are killed, provided they have not evaluated the `group_leader/1` BIF and are located on the local machine. Processes spawned on remote nodes will not be killed.
- **j** Lists all jobs. A list of all known jobs is printed. The current job name is prefixed with '*'.
- **s** Starts a new job. This will be assigned the new index [nn] which can be used in references.
- **r [node]** Starts a remote job on node. This is used in distributed Erlang to allow a shell running on one node to control a number of applications running on a network of nodes.
- **q** Quits Erlang.
- **?** Displays this message.
Exports

history(N) -> integer()

Types:
• N = integer()

Sets the number of previous commands to keep in the history list to N. The previous number is returned. The default number is 20.

results(N) -> integer()

Types:
• N = integer()

Sets the number of results from previous commands to keep in the history list to N. The previous number is returned. The default number is 20.
shell_default

Erlang Module

The functions in shell_default are called when no module name is given in a shell command.
Consider the following shell dialogue:

```
1 > lists:reverse("abc").
"cba"
2 > c(foo).
{ok, foo}
```

In command one, the module lists is called. In command two, no module name is specified. The shell searches the modules user_default followed by shell_default for the function foo/1.

shell_default is intended for “system wide” customizations to the shell.
user_default is intended for “local” or individual user customizations.

Hint

To add your own commands to the shell, create a module called user_default and add the commands you want. Then add the following line as the first line in your .erlang file in your home directory.

```
code:loadabs("$PATH/user_default").
```

$PATH is the directory where your user_default module can be found.
This module provides functions for starting Erlang slave nodes. All slave nodes which are started by a master will terminate automatically when the master terminates. All TTY output produced at the slave will be sent back to the master node. File I/O is done via the master.

Slave nodes on other hosts than the current one are started with the program `rsh`. The user must be allowed to `rsh` to the remote hosts without being prompted for a password. This can be arranged in a number of ways (refer to the `rsh` documentation for details). A slave node started on the same host as the master inherits certain environment values from the master, such as the current directory and the environment variables. For what can be assumed about the environment when a slave is started on another host, read the documentation for the `rsh` program.

An alternative to the `rsh` program can be specified on the command line to `erl` as follows: `-rsh Program`.

The slave node should use the same file system at the master. At least, Erlang/OTP should be installed in the same place on both computers and the same version of Erlang should be used.

Currently, a node running on Windows NT can only start slave nodes on the host on which it is running.

The master node must be alive.

Exports

**start(Host)**

Starts a slave node on the host `Host`. Host names need not necessarily be specified as fully qualified names; short names can also be used. This is the same condition that applies to names of distributed Erlang nodes. The name of the started node will be the same as the node which executes the call, with the exception of the host name part of the node name.

Return value: see `start/3`.

**start_link(Host)**

Starts a slave node on the host `Host` in the same way as the `start/1`, except that the slave node is linked to the currently executing process. If the process terminates, the slave node also terminates.

Return value: see `start/3`.

**start(Host, Name)**
Starts a slave node on the host Host with the name Name@Host.

Return value: see start/3.

\texttt{start\_link(Host, Name)}

Starts a slave node on the host Host in the same way as \texttt{start/2}, except that the slave node is linked to the currently executing process. If that process terminates, the slave node also terminates.

Return value: see start/3.

\texttt{start(Host, Name, Args) -&gt; \{ok, Node\} | \{error, ErrorInfo\}}

Starts a slave node with the name Name@Host on Host and passes the argument string Args to the new node.

The slave node resets its user process so that all terminal I/O which is produced at the slave is automatically relayed to the master. Also, the file process will be relayed to the master.

The Args argument can be used for a variety of purposes. See erl(1). For example, the following command line arguments can be passed to the slave:

- to set some environment variable on the slave
- to run some specific program on the slave
- to set some specific code path on the slave node.

As an example, suppose that we want to start a slave node at host H with the node name Name@H, and we also want the slave node to have the following properties:

- directory Dir should be added to the code path;
- the Mnesia directory should be set to M;
- the unix DISPLAY environment variable should be set to the display of the master node.

The following code is executed to achieve this:

\begin{verbatim}
E = " -env DISPLAY " ++ net_adm:localhost() ++ ":0 ",
Arg = "-mnesia_dir " ++ M ++ " -pa " ++ Dir ++ E,
slave:start(H, Name, Arg).
\end{verbatim}

The \texttt{start/3} call returns \{ok, Name@Host\} if successful, otherwise \{error, Reason\}. Reason can be one of:

- \texttt{timeout} The master node failed to get in contact with the slave node. This can happen in a number of circumstances:
  - Erlang/OTP is not installed on the remote host
  - the file system on the other host has a different structure to the the master
  - the Erlang nodes have different cookies.

- \texttt{no\_rsh} There is no \texttt{rsh} program on the computer.

- \texttt{already\_running, Name@Host} A node with the name Name@Host already exists.
Starts a slave node on the host Host in the same way as the start/3, except that the slave node is linked to the currently executing process. If that process terminates, the slave node also terminates.

Return value: see start/3.

stop(Node)

Stops (kills) a node.

pseudo([Master | ServerList])

Calls pseudo(Master, ServerList). If we want to start a node from the command line and set up a number of pseudo servers, an Erlang runtime system can be started as follows:

```
% erl -name abc -s slave pseudo klacke@super x --
```

pseudo(Master, ServerList)

Starts a number of pseudo servers. A pseudo server is a server with a registered name which does absolutely nothing but pass on all message to the real server which executes at a master node. A pseudo server is an intermediary which only has the same registered name as the real server.

For example, if we have started a slave node \(N\) and want to execute pxw graphics code on this node, we can start the server pxw_server as a pseudo server at the slave node. The following code illustrates:

```
rpc:call(N, slave, pseudo, [node(), [pxw_server]]).
```

relay(Pid)

Runs a pseudo server. This function never returns any value and the process which executes the function will receive messages. All messages received will simply be passed on to Pid.
The sofs module implements operations on finite sets and relations represented as sets. Intuitively, a set is a collection of elements; every element belongs to the set, and the set contains every element.

Given a set $A$ and a sentence $S(x)$, where $x$ is a free variable, a new set $B$ whose elements are exactly those elements of $A$ for which $S(x)$ holds can be formed, this is denoted $B = \{ x \in A : S(x) \}$. Sentences are expressed using the logical operators “for some” (or “there exists”), “for all”, “and”, “or”, “not”. If the existence of a set containing all the specified elements is known (as will always be the case in this module), we write $B = \{ x : S(x) \}$.

The unordered set containing the elements $a$, $b$ and $c$ is denoted $\{ a, b, c \}$. This notation is not to be confused with tuples. The ordered pair of $a$ and $b$, with first coordinate $a$ and second coordinate $b$, is denoted $(a, b)$. An ordered pair is an ordered set of two elements. In this module ordered sets can contain one, two or more elements, and parentheses are used to enclose the elements. Unordered sets and ordered sets are orthogonal, again in this module; there is no unordered set equal to any ordered set.

The set that contains no elements is called the empty set. If two sets $A$ and $B$ contain the same elements, then $A$ is equal to $B$, denoted $A = B$. Two ordered sets are equal if they contain the same number of elements and have equal elements at each coordinate. If a set $A$ contains all elements that $B$ contains, then $B$ is a subset of $A$. The union of two sets $A$ and $B$ is the smallest set that contains all elements of $A$ and all elements of $B$. The intersection of two sets $A$ and $B$ is the set that contains all elements of $A$ that belong to $B$. Two sets are disjoint if their intersection is the empty set. The difference of two sets $A$ and $B$ is the set that contains all elements of $A$ that do not belong to $B$. The symmetric difference of two sets is the set that contains those elements that belong to either of the two sets, but not both. The union of a collection of sets is the smallest set that contains all the elements that belong to at least one set of the collection. The intersection of a non-empty collection of sets is the set that contains all elements that belong to every set of the collection.

The Cartesian product of two sets $X$ and $Y$, denoted $X \times Y$, is the set $\{ a : a = (x, y) \text{ for some } x \in X \text{ and for some } y \in Y \}$. A relation is a subset of $X \times Y$. Let $R$ be a relation. The fact that $(x, y)$ belongs to $R$ is written as $x R y$. Since relations are sets, the definitions of the last paragraph (subset, union, and so on) apply to relations as well. The domain of $R$ is the set $\{ x : x R y \text{ for some } y \in Y \}$. The range of $R$ is the set $\{ y : x R y \text{ for some } x \in X \}$. The converse of $R$ is the set $\{ a : a = (y, x) \text{ for some } (x, y) \in R \}$. If $A$ is a subset of $X$, then the image of $A$ under $R$ is the set $\{ y : x R y \text{ for some } x \in A \}$, and if $B$ is a subset of $Y$, then the inverse image of $B$ is the set $\{ x : x R y \text{ for some } y \in B \}$. If $R$ is a relation from $X$ to $Y$ and $S$ is a relation from $Y$ to $Z$, then the relative product of $R$ and $S$ is the relation $T$ from $X$ to $Z$ defined so that $x T z$ if and only if there exists an element $y$ in $Y$ such that $x R y$ and $y S z$. The restriction of $R$ to $A$ is the set $S$ defined so that $x S y$ if and only if there exists an element $x$ in $A$ such that $x R y$. If $X = Y$ then we call $R$ a relation in $X$. The field of a relation $R$ in $X$ is the union of the domain of $R$ and
the range of R. If R is a relation in X, and if S is defined so that x S y if x R y and not x = y, then S is the strict relation corresponding to R, and vice versa, if S is a relation in X, and if R is defined so that x R y if x S y or x = y, then R is the weak relation corresponding to S. A relation R in X is reflexive if x R x for every element x of X; it is symmetric if x R y implies that y R x; and it is transitive if x R y and y R z imply that x R z.

A function F is a relation, a subset of X × Y, such that the domain of F is equal to X and such that for every x in X there is a unique element y in Y with (x, y) in F. The latter condition can be formulated as follows: if x F y and x F z then y = z. In this module, it will not be required that the domain of F be equal to X for a relation to be considered a function. Instead of writing (x, y) in F or x F y, we write F(x) = y when F is a function, and say that F maps x onto y, or that the value of F at x is y. Since functions are relations, the definitions of the last paragraph (domain, range, and so on) apply to functions as well. If the converse of a function F is a function F’, then F’ is called the inverse of F. The relative product of two functions F1 and F2 is called the composite of F1 and F2 if the range of F1 is a subset of the domain of F2.

Sometimes, when the range of a function is more important than the function itself, the function is called a family. The domain of a family is called the index set, and the range is called the indexed set. If x is a family from I to X, then x[i] denotes the value of the function at index i. The notation “a family in X” is used for such a family. When the indexed set is a set of subsets of a set X, then we call x a family of subsets of X. If x is a family of subsets of X, then the union of the range of x is called the union of the family x. If x is non-empty (the index set is non-empty), the intersection of the family x is the intersection of the range of x. In this module, the only families that will be considered are families of subsets of some set X; in the following the word “family” will be used for such families of subsets.

A partition of a set X is a collection S of non-empty subsets of X whose union is X and whose elements are pairwise disjoint. A relation in a set is an equivalence relation if it is reflexive, symmetric and transitive. If R is an equivalence relation in X, and x is an element of X, the equivalence class of x with respect to R is the set of all those elements y of X for which x R y holds. The equivalence classes constitute a partitioning of X. Conversely, if C is a partition of X, then the relation that holds for any two elements of X if they belong to the same equivalence class, is an equivalence relation induced by the partition C. If R is an equivalence relation in X, then the canonical map is the function that maps every element of X onto its equivalence class.

Relations as defined above (as sets of ordered pairs) will from now on be referred to as binary relations. We call a set of ordered sets (x[1], ..., x[n]) an (n-ary) relation, and say that the relation is a subset of the Cartesian product X[1] × ... × X[n] where x[i] is an element of X[i], 1 ≤ i ≤ n. The projection of an n-ary relation R onto coordinate i is the set {x[i] : (x[1], ..., x[i], ..., x[n]) in R for some x[j] in X[j], 1 ≤ j ≤ n and not i = j}. The projections of a binary relation R onto the first and second coordinates are the domain and the range of R respectively. The relative product of binary relations can be generalized to n-ary relations as follows. Let TR be a an ordered set (R[1], ..., R[n]) of binary relations from X to Y[i] and S a binary relation from (Y[1] × ... × Y[n]) to Z. The relative product of TR and S is the binary relation T from X to Z defined so that x T z if and only if there exists an element y[i] in Y[i] for each 1 ≤ i ≤ n such that x R[i] y[i] and (y[1], ..., y[n]) S z. Now let TR be a an ordered set (R[1], ..., R[n]) of binary relations from X[i] to Y[i] and S a subset of X[1] × ... × X[n]. The multiple relative product of TR and and S is defined to be the set (z : z = ((x[1], ..., x[n]), (y[1], ..., y[n])) for some (x[1], ..., x[n]) in S and for some (x[i], y[i]) in R[i], 1 ≤ i ≤ n). The natural join of an n-ary relation R and an m-ary relation S on
coordinate i and j is defined to be the set \( \{ z : z = (x[1], ..., x[n], y[1], ..., y[j-1], y[j+1], ..., y[m]) \} \) for some \( (x[1], ..., x[n]) \) in \( R \) and for some \( (y[1], ..., y[m]) \) in \( S \) such that \( x[i] = y[j] \).

The sets recognized by this module will be represented by elements of the relation Sets, defined as the smallest set such that:

- for every atom \( T \) except `'-'` and for every term \( X, (T, X) \) belongs to Sets (atomic sets);
- \( \{ ('-', []) \} \) belongs to Sets (the untyped empty set);
- for every tuple \( T = \{ T[1], ..., T[n] \} \) and for every tuple \( X = \{ X[1], ..., X[n] \} \), if \( (T[i], X[i]) \) belongs to Sets for every \( 1 \leq i \leq n \) then \( (T, X) \) belongs to Sets (ordered sets);
- for every term \( T \), if \( X \) is the empty list or a non-empty sorted list \( \{ X[1], ..., X[n] \} \) without duplicates such that \( (T, X[i]) \) belongs to Sets for every \( 1 \leq i \leq n \), then \( ([T], X) \) belongs to Sets (typed unordered sets).

An external set is an element in the range of Sets. A type is an element in the domain of Sets. If \( S \) is an element \( (T, X) \) of Sets, then \( T \) is a valid type of \( X \), \( T \) is the type of \( S \), and \( X \) is the external set of \( S \). from_term/2 [page 226] creates a set from a type and an Erlang term turned into an external set.

The actual sets represented by Sets are the elements of the range of the function Set from Sets to Erlang terms and sets of Erlang terms:

- \( \text{Set}(T, \text{Term}) = \text{Term} \), where \( T \) is an atom;
- \( \text{Set}(\{ T[1], ..., T[n] \}, \{ X[1], ..., X[n] \}) = (\text{Set}(T[1], X[1]), ..., \text{Set}(T[n], X[n])) \);
- \( \text{Set}(\{ T \}, \{ X[1], ..., X[n] \}) = (\text{Set}(T, X[1]), ..., \text{Set}(T, X[n])) \);
- \( \text{Set}(\{ T \}, []) = \{ \} \).

When there is no risk of confusion, elements of Sets will be identified with the sets they represent. For instance, if \( U \) is the result of calling union/2 with \( S1 \) and \( S2 \) as arguments, then \( U \) is said to be the union of \( S1 \) and \( S2 \). A more precise formulation would be that \( \text{Set}(U) \) is the union of \( \text{Set}(S1) \) and \( \text{Set}(S2) \).

The types are used to implement the various conditions that sets need to fulfill. As an example, consider the relative product of two sets \( R \) and \( S \), and recall that the relative product of \( R \) and \( S \) is defined if \( R \) is a binary relation to \( Y \) and \( S \) is a binary relation from \( Y \). The function that implements the relative product, relative_product/2 [page 232], checks that the arguments represent binary relations by matching \( \{ A, B \} \) against the type of the first argument (Arg1 say), and \( \{ C, D \} \) against the type of the second argument (Arg2 say). The fact that \( \{ A, B \} \) matches the type of Arg1 is to be interpreted as Arg1 representing a binary relation from \( X \) to \( Y \), where \( X \) is defined as all sets \( \text{Set}(x) \) for some element \( x \) in \( S \) the type of which is \( A \), and similarly for \( Y \). In the same way Arg2 is interpreted as representing a binary relation from \( W \) to \( Z \). Finally it is checked that \( B \) matches \( C \), which is sufficient for ensuring that \( W \) is equal to \( Y \). The untyped empty set is handled separately: its type, `-' matches the type of any unordered set.

A few functions of this module (drestriction/3, family_projection/2, partition/2, partition_family/2, projection/2, restriction/3, substitution/2) accept Erlang functions as a means to modify each element of a given unordered set. Such a function, called SetFun in the following, can be specified as a function, a tuple \( \{ \text{external}, \text{Fun} \} \), or an integer. The two latter alternatives are
optimizations; instead of a set, the argument presented to the function is an external set, which in the present implementation can be done more efficiently. This optimization can however only be applied when the elements of the unordered set are atomic or ordered sets. It must also be the case that the type of the elements matches some clause of Fun (the type of the created set is the result of applying Fun to the type of the given set), and that Fun does nothing but selecting, duplicating or rearranging parts of the elements. Specifying a SetFun as an integer I is equivalent to specifying \{external, fun(X) -> element(I, X)\}, but is to be preferred since it makes it possible to handle this case even more efficiently. Examples of SetFuns:

\[
\{
\text{sofs, union}
\}
\]
\[
\text{fun}(S) \to \text{sofs:partition}(1, S) \text{ end}
\]
\[
\{
\text{external, fun}(A) \to A \text{ end}
\}
\]
\[
\{
\text{external, fun}([A,\ldots,C]) \to \{C,A\} \text{ end}
\}
\]
\[
\{
\text{external, fun}([],\ldots,[C]) \to C \text{ end}
\}
\]
\[
\{
\text{external, fun}([],\ldots,[\{E\}=C]) \to \{E,\{E\}\} \text{ end}
\}
\]

2

The order in which functions are applied to elements is not specified, and may change in future versions of sofs.

The execution time of the functions of this module is dominated by the time it takes to sort lists. When no sorting is needed, the execution time is in the worst case proportional to the sum of the sizes of the input arguments and the returned value. A few functions execute in constant time: from\_external, is\_empty\_set, is\_set, is\_sofs\_set, to\_external, type.

The functions of this module exit the process with a badarg, bad\_function, or type\_mismatch message when given badly formed arguments or sets the types of which are not compatible.

Types

\[
\text{anyset()} = - \text{an unordered, ordered or atomic set} -
\]
\[
\text{binary\_relation()} = - \text{a binary relation} -
\]
\[
\text{bool()} = \text{true} \mid \text{false}
\]
\[
\text{external\_set()} = - \text{an external set} -
\]
\[
\text{family()} = - \text{a family (of subsets)} -
\]
\[
\text{function()} = - \text{a function} -
\]
\[
\text{ordset()} = - \text{an ordered set} -
\]
\[
\text{relation()} = - \text{an n-ary relation} -
\]
\[
\text{set() = - an unordered set -}
\]
\[
\text{set\_of\_sets()} = - \text{an unordered set of set()} -
\]
\[
\text{set\_fun()} = \text{integer()} \geq 1
\]
\[
\mid \{\text{external, fun(external\_set())} \to \text{external\_set()}
\]
\[
\mid \text{fun(anyset())} \to \text{anyset()}
\]
\[
\text{spec\_fun()} = \{\text{external, fun(external\_set())} \to \text{bool()}
\]
\[
\mid \text{fun(anyset())} \to \text{bool()}
\]
\[
\text{type()} = - \text{a type} -
\]

Exports

\[
\text{a\_function(Tuples [, Type])} \to \text{Function}
\]

Types:
- Function = function()
- Tuples = [tuple()]
- Type = type()

Creates a function [page 216]. \texttt{a.function(F, T)} is equivalent to \texttt{from\_term(F, T)}, if the result is a function. If no type [page 217] is explicitly given, \{[atom, atom]\} is used as type of the function.

\texttt{canonical\_relation(SetOfSets)} \rightarrow BinRel

Types:
- BinRel = binary\_relation()
- SetOfSets = set\_of\_sets()

Returns the binary relation containing the elements (E, Set) such that Set belongs to SetOfSets and E belongs to Set. If SetOfSets is a partition [page 216] of a set X and R is the equivalence relation in X induced by SetOfSets, then the returned relation is the canonical map [page 216] from X onto the equivalence classes with respect to R.

\begin{verbatim}
1> Ss = sofs:from\_term([[a,b],[b,c]]),
   CR = sofs:canonical\_relation(Ss),
   sofs:to\_external(CR).
\end{verbatim}

\texttt{composite(Function1, Function2)} \rightarrow Function3

Types:
- Function1 = Function2 = Function3 = function()

Returns the composite [page 216] of the functions Function1 and Function2.

\begin{verbatim}
1> F1 = sofs:a\_function([[a,1],[b,2],[c,2]]),
   F2 = sofs:a\_function([[1,x],[2,y],[3,z]]),
   F = sofs:composite(F1, F2),
   sofs:to\_external(F).
\end{verbatim}

\texttt{constant\_function(Set, AnySet)} \rightarrow Function

Types:
- AnySet = anyset()
- Function = function()
- Set = set()

Creates the function [page 216] that maps each element of the set Set onto AnySet.

\begin{verbatim}
1> S = sofs:set([a,b]),
   E = sofs:from\_term(1),
   R = sofs:constant\_function(S, E),
   sofs:to\_external(R).
\end{verbatim}

\texttt{converse(BinRel1)} \rightarrow BinRel2

Types:
- BinRel1 = BinRel2 = binary\_relation()
Returns the converse [page 215] of the binary relation BinRel1.

```prolog
1> R1 = sofs:relation([\{1,a\},\{2,b\},\{3,a\}]),
R2 = sofs:converse(R1),
sofs:to_external(R2).
\{[a,1],[a,3],[b,2]\}
```

difference(Set1, Set2) -> Set3

Types:
- Set1 = Set2 = Set3 = set()

Returns the difference [page 215] of the sets Set1 and Set2.

digraph_to_family(Graph [, Type]) -> Family

Types:
- Graph = digraph() - see digraph(3) -
- Family = family()
- Type = type()

Creates a family [page 216] from the directed graph Graph. Each vertex a of Graph is represented by a pair (a, [b[1], ..., b[n]]) where the b[i]'s are the out-neighbours of a. digraph_to_family(G) is equivalent to digraph_to_family(G, [[atom, [atom]]]). It is assumed that Type is a valid type [page 217] of the external set of the family.

If G is a directed graph, it holds that the vertices and edges of G are the same as the vertices and edges of family_to_digraph(digraph_to_family(G)).

domain(BinRel) -> Set

Types:
- BinRel = binary_relation()
- Set = set()

Returns the domain [page 215] of the binary relation BinRel.

```prolog
1> R = sofs:relation([\{1,a\},\{1,b\},\{2,b\},\{2,c\}]),
S = sofs:domain(R),
sofs:to_external(S).
\{1,2\}
```

drestriction(BinRel1, Set) -> BinRel2

Types:
- BinRel1 = BinRel2 = binary_relation()
- Set = set()

Returns the difference between the binary relation BinRel1 and the restriction [page 215] of BinRel1 to Set; drestriction(R, S) is equivalent to difference(R, restriction(R, S)).

```prolog
1> R1 = sofs:relation([\{1,a\},\{2,b\},\{3,c\}]),
S = sofs:set([2,4,6]),
R2 = sofs:drestriction(R1, S),
sofs:to_external(R2).
\{[1,a],[3,c]\}
```
drestriction(SetFun, Set1, Set2) -> Set3

Types:
  • SetFun = set_fun()
  • Set1 = Set2 = Set3 = set()

Returns a subset of Set1 containing those elements that do not yield an element in Set2
as the result of applying SetFun; drestriction(F, S1, S2) is equivalent to
difference(S1, restriction(F, S1, S2)).

1> SetFun = {external, fun([A,B,C]) -> [B,C] end},
R1 = sofs:relation([[[a,aa,1]],[[b,bb,2],[c,cc,3]]]),
R2 = sofs:relation([[[bb,2],[cc,3],[dd,4]]]),
R3 = sofs:drestriction(SetFun, R1, R2),
sofs:to_external(R3).
[[a,aa,1]]

empty_set() -> Set

Types:
  • Set = set()

Returns the untyped empty set [page 217]. empty_set() is equivalent to
from_term([], [])

family(Tuples [, , Type]) -> Family

Types:
  • Family = family()
  • Tuples = [tuple()]
  • Type = type()

Creates a family of subsets [page 216]. family(F, T) is equivalent to from_term(F,
T), if the result is a family. If no type [page 217] is explicitly given, [[atom, [atom]]]
is used as type of the family.

family_difference(Family1, Family2) -> Family3

Types:
  • Family1 = Family2 = Family3 = family()

If Family1 and Family2 are families [page 216], then Family3 the family such that the
index set is equal to the index set of Family1, and Family3[i] is the difference between
Family1[i] and Family2[i] if Family2 maps i, Family1[i] otherwise.

1> F1 = sofs:family([[a,[1,2]],[b,[3,4]]]),
F2 = sofs:family([[b,[4,5]],[c,[6,7]]]),
F3 = sofs:family_difference(F1, F2),
sofs:to_external(F3).
[[a,[1,2]],[b,[3]]]

family_domain(Family1) -> Family2

Types:
  • Family1 = Family2 = family()
If Family1 is a family [page 216] and Family1[i] is a binary relation for every i in the index set of Family1, then Family2 is the family with the same index set as Family1 such that Family2[i] is the domain [page 215] of Family1[i].

1> FR = sofs:from_term([[a,[[1,a],[2,b],[3,c]]],[b,[]],[c,[[4,d],[5,e]]]]),
F = sofs:family(FR),
sofs:to_external(F).
[[a,[1,2,3]],[b,[]],[c,[4,5]]]

family_field(Family1) -> Family2

Types:
- Family1 = Family2 = family()

If Family1 is a family [page 216] and Family1[i] is a binary relation for every i in the index set of Family1, then Family2 is the family with the same index set as Family1 such that Family2[i] is the field [page 215] of Family1[i]. family_field(Family1) is equivalent to family_union(family_domain(Family1), family_range(Family1)).

1> FR = sofs:from_term([[a,[[1,a],[2,b],[3,c]]],[b,[]],[c,[[4,d],[5,e]]]]),
F = sofs:family_field(FR),
sofs:to_external(F).
[[a,[1,2,3,a,b,c]],[b,[]],[c,[4,5,d,e]]]

family_intersection(Family1) -> Family2

Types:
- Family1 = Family2 = family()

If Family1 is a family [page 216] and Family1[i] is a set of sets for every i in the index set of Family1, then Family2 is the family with the same index set as Family1 such that Family2[i] is the intersection [page 215] of Family1[i].

If Family1[i] is an empty set for some i, then the process exits with a badarg message.

1> F1 = sofs:from_term([[a,[[1,2,3],[2,3,4]]],[b,[[x,y],[x,y]]]]),
F2 = sofs:family_intersection(F1),
sofs:to_external(F2).
[[a,[2,3]],[b,[x,y]]]

family_intersection(Family1, Family2) -> Family3

Types:
- Family1 = Family2 = Family3 = family()

If Family1 and Family2 are families [page 216], then Family3 is the family such that the index set is the intersection of Family1’s and Family2’s index sets, and Family3[i] is the intersection of Family1[i] and Family2[i].

1> F1 = sofs:family([[a,[[1,2]],[b,[3,4]],[c,[5,6]]]]),
F2 = sofs:family([[b,[[4,5]],[c,[7,8]],[d,[9,10]]]]),
F3 = sofs:family_intersection(F1, F2),
sofs:to_external(F3).
[[b,[4]],[c,[]]]

family_projection(SetFun, Family1) -> Family2
Types:
- SetFun = set_fun()
- Family1 = Family2 = family()
- Set = set()

If Family1 is a family [page 216] then Family2 is the family with the same index set as Family1 such that Family2[i] is the result of calling SetFun with Family1[i] as argument.

```
1> F1 = sofs:from_term([[[a,[[1,2],[2,3]]],[b,[]]]]),
   F2 = sofs:family_projection([sofs, union], F1),
   sofs:to_external(F2).
[[a,[1,2,3]],[b,[[]]]]
```

family_range(Family1) -> Family2

Types:
- Family1 = Family2 = family()

If Family1 is a family [page 216] and Family1[i] is a binary relation for every i in the index set of Family1, then Family2 is the family with the same index set as Family1 such that Family2[i] is the range [page 215] of Family1[i].

```
1> FR = sofs:from_term([[[a,[[1,a],[2,b],[3,c]]],[b,[]],[c,[[4,d],[5,e]]]]]),
   F = sofs:family_range(FR),
   sofs:to_external(F).
[[a,[[a,b,c]],[b,[]],[c,[d,e]]]]
```

family_specification(Fun, Family1) -> Family2

Types:
- Fun = spec_fun()
- Family1 = Family2 = family()

If Family1 is a family [page 216], then Family2 is the restriction [page 215] of Family1 to those elements i of the index set for which Fun applied to Family1[i] returns true. If Fun is a tuple {external, Fun2}, Fun2 is applied to the external set [page 217] of Family1[i], otherwise Fun is applied to Family1[i].

```
1> F1 = sofs:family([[a,[1,2,3]],[b,[1,2]],[c,[1]]]),
   SpecFun = fun(S) -> sofs:no_elements(S) =:= 2 end,
   F2 = sofs:family_specification(SpecFun, F1),
   sofs:to_external(F2).
[[b,[1,2]]]
```

family_to_digraph(Family [, GraphType]) -> Graph

Types:
- Graph = digraph()
- Family = family()
- GraphType = - see digraph(3) -

```
Creates a directed graph from the family [page 216] Family. For each pair
(a, (b[1], ..., b[n])) of Family, the vertex a as well the edges (a, b[i]) for 1 ≤ i ≤ n
are added to a newly created directed graph.

If no graph type is given, digraph:new/1 is used for creating the directed graph,
otherwise the GraphType argument is passed on as second argument to
digraph:new/2.

If F is a family, it holds that F is a subset of
digraph_to_family(family_to_digraph(F), type(F)). Equality holds if
union_of_family(F) is a subset of domain(F).

Creating a cycle in an acyclic graph exits the process with a cyclic message.

family_to_relation(Family) -> BinRel

Types:
- Family = family()
- BinRel = binary_relation()
If Family is a family [page 216], then BinRel is the binary relation containing all pairs
(i, x) such that i belongs to the index set of Family and x belongs to Family[i].

1> F = sofs:family([[a,[]],[b,[1]],[c,[2,3]]]),
R = sofs:family_to_relation(F),
sofs:to_external(R).
[[b,1],[c,2],[c,3]]

family_union(Family1) -> Family2

Types:
- Family1 = Family2 = family()
If Family1 is a family [page 216] and Family1[i] is a set of sets for each i in the index set
of Family1, then Family2 is the family with the same index set as Family1 such that
Family2[i] is the union [page 215] of Family1[i]; family_union(F) is equivalent to
family_projection([sofs,union], F).

1> F1 = sofs:from_term([[a,[[1,2],[2,3]]],[b,[]]]),
F2 = sofs:family_union(F1),
sofs:to_external(F2).
[[a,[1,2,3]],[b,[]]]

family_union(Family1, Family2) -> Family3

Types:
- Family1 = Family2 = Family3 = family()
If Family1 and Family2 are families [page 216], then Family3 is the family such that the
index set is the union of Family1's and Family2's index sets, and Family3[i] is the union
of Family1[i] and Family2[i] if both maps i, Family1[i] or Family2[i] otherwise.

1> F1 = sofs:family([a,[[1,2]],[b,[3,4]],[c,[5,6]]]),
F2 = sofs:family([[b,[4,5]],[c,[7,8]],[d,[9,10]]]),
F3 = sofs:family_union(F1, F2),
sofs:to_external(F3).
[[a,[1,2]],[b,[3,4,5]],[c,[5,6,7,8]],[d,[9,10]]]
field(BinRel) -> Set

Types:
- BinRel = binary_relation()
- Set = set()

Returns the field [page 215] of the binary relation BinRel; field(R) is equivalent to union(domain(R), range(R)).

1> R = sofs:relation([[1,a],[1,b],[2,b],[2,c]]),
   S = sofs:field(R),
   sofs:to_external(S).
   [1,2,a,b,c]

from_external(ExternalSet, Type) -> AnySet

Types:
- ExternalSet = external_set()
- AnySet = anyset()
- Type = type()

Creates a set from the external set [page 217] ExternalSet and the type [page 217] Type. It is assumed that Type is a valid type [page 217] of ExternalSet.

from_sets(ListOfSets) -> Set

Types:
- Set = set()
- ListOfSets = [anyset()]

Returns the unordered set [page 217] containing the sets of the list ListOfSets.

1> S1 = sofs:relation([[[a,1],[b,2]]]),
   S2 = sofs:relation([[[x,3],[y,4]]]),
   S = sofs:from_sets([S1,S2]),
   sofs:to_external(S).
   [[[a,1],[b,2]],[[x,3],[y,4]]]

from_sets(TupleOfSets) -> Ordset

Types:
- Ordset = ordset()
- TupleOfSets = tuple-of(anyset())

Returns the ordered set [page 217] containing the sets of the non-empty tuple TupleOfSets.

from_term(Term [, Type]) -> AnySet

Types:
- AnySet = anyset()
- Term = term()
- Type = type()
sofs STDLIB Reference Manual

Creates an element of Sets [page 217] by traversing the term Term, sorting lists, removing duplicates and deriving or verifying a valid type [page 217] for the so obtained external set. from_term(T) is equivalent to from_term(T, [',']). An explicitly given type [page 217] Type can be used to limit the depth of the traversal; an atomic type stops the traversal, as demonstrated by this example where “foo” and {“foo”} are left unmodified:

```
1> S = sofs:from_term([[“foo”],[1,1]],[“foo”,[2,2]]),
    sofs:to_external(S).
[[[“foo”],[1]],[“foo”,[2]]]
```

from_term can be used for creating atomic or ordered sets. The only purpose of such a set is that of later building unordered sets since all functions in this module that do anything operate on unordered sets. Creating unordered sets from a collection of ordered sets may be the way to go if the ordered sets are big and one does not want to waste heap by rebuilding the elements of the unordered set. An example showing that a set can be built “layer by layer”:

```
1> A = sofs:from_term(a),
   S = sofs:set([1,2,3]),
P1 = sofs:from_sets([A,S]),
P2 = sofs:from_term([b,[6,5,4]]),
   Ss = sofs:from_sets([P1,P2]),
    sofs:to_external(Ss).
[a,[1,2,3]],[b,[4,5,6]]
```

Other functions that create sets are from_external/2 and from_sets/1. Special cases of from_term/2 are a_function/1,2, empty_set/0, family/1,2, relation/1,2, and set/1,2.

image(BinRel, Set1) -> Set2

Types:
- BinRel = binary relation()
- Set1 = Set2 = set()

Returns the image [page 215] of the set Set1 under the binary relation BinRel.

```
1> R = sofs:relation([[1,a],[2,b],[2,c],[3,d]]),
   S1 = sofs:set([1,2]),
   S2 = sofs:image(R, S1),
    sofs:to_external(S2).
[a,b,c]
```

intersection(SetOfSets) -> Set

Types:
- Set = set()
- SetOfSets = set_of_sets()

Returns the intersection [page 215] of the set of sets SetOfSets. Intersecting an empty set of sets exits the process with a badarg message.

intersection(Set1, Set2) -> Set3

Types:
Set1 = Set2 = Set3 = set()

Returns the intersection [page 215] of Set1 and Set2.

intersection_of_family(Family) -> Set

Types:
- Family = family()
- Set = set()

Returns the intersection of the family [page 216] Family. Intersecting an empty family exits the process with a badarg message.

1> F = sofs:family([[a,[0,2,4]],[b,[0,1,2]],[c,[2,3]]]),
   S = sofs:intersection_of_family(F),
   sofs:to_external(S).
   [2]

inverse(Function1) -> Function2

Types:
- Function1 = Function2 = function()

Returns the inverse [page 216] of the function Function1.

1> R1 = sofs:relation([[1,a],[2,b],[3,c]]),
   R2 = sofs:inverse(R1),
   sofs:to_external(R2).
   [{a,1},{b,2},{c,3}]

inverse_image(BinRel, Set1) -> Set2

Types:
- BinRel = binary_relation()
- Set1 = Set2 = set()

Returns the inverse image [page 215] of Set1 under the binary relation BinRel.

1> R = sofs:relation([[1,a],[2,b],[2,c],[3,d]]),
   S1 = sofs:set([c,d,e]),
   S2 = sofs:inverse_image(R, S1),
   sofs:to_external(S2).
   [2,3]

is_a_function(BinRel) -> Bool

Types:
- Bool = bool()
- BinRel = binary_relation()

Returns true if the binary relation BinRel is a function [page 216] or the untyped empty set, false otherwise.

is_disjoint(Set1, Set2) -> Bool

Types:
is_empty_set(AnySet) -> Bool
Types:
  • AnySet = anyset()
  • Bool = bool()
Returns true if Set is an empty unordered set, false otherwise.

is_equal(AnySet1, AnySet2) -> Bool
Types:
  • AnySet1 = AnySet2 = anyset()
  • Bool = bool()
Returns true if the AnySet1 and AnySet2 are equal [page 215], false otherwise.

is_set(AnySet) -> Bool
Types:
  • AnySet = anyset()
  • Bool = bool()
Returns true if AnySet is an unordered set [page 217], and false if AnySet is an ordered set or an atomic set.

is_sofs_set(Term) -> Bool
Types:
  • Bool = bool()
  • Term = term()
Returns true if Term is an unordered set [page 217], an ordered set or an atomic set, false otherwise.

is_subset(Set1, Set2) -> Bool
Types:
  • Bool = bool()
  • Set1 = Set2 = set()
Returns true if Set1 is a subset [page 215] of Set2, false otherwise.

is_type(Term) -> Bool
Types:
  • Bool = bool()
  • Term = term()
Returns true if the term Term is a type [page 217].

join(Relation1, I, Relation2, J) -> Relation3
Types:
- Relation1 = Relation2 = Relation3 = relation()
- I = J = integer() > 0

Returns the natural join [page 216] of the relations Relation1 and Relation2 on coordinates I and J.

```erl
1> R1 = sofs:relation([[a,x,1],[b,y,2]]),
   R2 = sofs:relation([[1,f,g],[1,h,i],[2,3,4]]),
   J = sofs:join(R1, 3, R2, 1),
   sofs:to_external(J),
   [{a,x,1,f,g}, {a,x,1,h,i}, {b,y,2,3,4}]
```

multiple_relative_product(TupleOfBinRels, BinRel1) -> BinRel2

Types:
- TupleOfBinRels = tuple-of(BinRel)
- BinRel = BinRel1 = BinRel2 = binary relation()

If TupleOfBinRels is a non-empty tuple \{R[1], ..., R[n]\} of binary relations and BinRel1 is a binary relation, then BinRel2 is the multiple relative product [page 216] of the ordered set \(\langle R[i], ..., R[n]\rangle\) and BinRel1.

```erl
1> Ri = sofs:relation([[a,1],[b,2],[c,3]]),
   R = sofs:relation([[a,b],[b,c],[c,a]]),
   MP = sofs:multiple_relative_product(Ri, Ri, R),
   sofs:to_external(sofs:range(MP)),
   [[1,2],[2,3],[3,1]]
```

no_elements(ASet) -> NoElements

Types:
- ASet = set() | ordset()
- NoElements = integer() >= 0

Returns the number of elements of the ordered or unordered set ASet.

```erl
partition(SetOfSets) -> Partition
```

Types:
- SetOfSets = set_of_sets()
- Partition = set()

Returns the partition [page 216] of the union of the set of sets SetOfSets such that two elements are considered equal if they are members of the same elements of SetOfSets.

```erl
1> Sets1 = sofs:from_term([[a,b,c],[d,e,f],[g,h,i]]),
   Sets2 = sofs:from_term([[b,c,d],[e,f,g],[h,i,j]]),
   P = sofs:partition(sofs:union(Sets1, Sets2)),
   sofs:to_external(P),
   [[[a],[b,c],[d]], [[e,f],[g]], [[h,i],[j]]]
```

partition(SetFun, Set) -> Partition

Types:
Returns the partition (page 216) of Set such that two elements are considered equal if the results of applying SetFun are equal.

```erlang
1> Ss = sofs:from_term([[a],[b],[c,d],[e,f]]),
   SetFun = fun(S) -> sofs:from_term(sofs:no_elements(S)) end,
   P = sofs:partition(SetFun, Ss),
   sofs:to_external(P).
[[[a],[b]],[[c,d],[e,f]]]
```

**partition_family(SetFun, Set) -> Family**

Types:
- Family = family()
- SetFun = set_fun()
- Set = set()

Returns the family (page 216) Family where the indexed set is a partition (page 216) of Set such that two elements are considered equal if the results of applying SetFun are the same value. This i is the index that Family maps onto the equivalence class (page 216).

```erlang
1> S = sofs:relation([[[a],a,a,a],[a,a,b,b],[a,b,b,b]]),
   SetFun = fun(A, C) -> [A,C] end,
   P = sofs:partition_family(SetFun, S),
   sofs:to_external(P).
[[[a],[a,a,a]],[[a,b],[a,a,a],[a,b,b,b]]]
```

**product(TupleOfSets) -> Relation**

Types:
- Relation = relation()
- TupleOfSets = tuple-of(set())

Returns the Cartesian product (page 216) of the non-empty tuple of sets TupleOfSets. If \((x[1],...,x[n])\) is an element of the n-ary relation Relation, then \(x[i]\) is drawn from element \(i\) of TupleOfSets.

```erlang
1> S1 = sofs:set([a,b]),
   S2 = sofs:set([1,2]),
   S3 = sofs:set([x,y]),
   P3 = sofs:product([S1,S2,S3]),
   sofs:to_external(P3).
[[[a,1],[a,1],[a,2],[a,2],[b,1],[b,1],[b,2],[b,2]]]
```

**product(Set1, Set2) -> BinRel**

Types:
- BinRel = binary_relation()
- Set1 = Set2 = set()

Returns the Cartesian product (page 215) of Set1 and Set2. product(Set1, Set2) is equivalent to product([Set1, Set2]).
S1 = sofs:set([1,2]),
S2 = sofs:set([a,b]),
R = sofs:product(S1, S2),
sofs:to_external(R).

[[1,1,a], [1,1,b], [2,2,a], [2,2,b]]

projection(SetFun, Set1) -> Set2
Types:
• SetFun = set()fun()
• Set1 = Set2 = set()
Returns the set created by substituting each element of Set1 by the result of applying SetFun to the element.
If SetFun is a number i > 1 and Set1 is a relation, then the returned set is the projection [page 216] of Set1 onto coordinate i.

S1 = sofs:from_term([[1,a],[2,b],[3,a]]),
S2 = sofs:projection(2, S1),
sofs:to_external(S2).
[a,b]

range(BinRel) -> Set
Types:
• BinRel = binary_relation()
• Set = set()
Returns the range [page 215] of the binary relation BinRel.

R = sofs:relation([[1,a],[1,b],[2,b],[2,c]]),
S = sofs:range(R),
sofs:to_external(S).
[a,b,c]

relation(Tuples [, Type]) -> Relation
Types:
• N = integer()
• Type = N | type()
• Relation = relation()
• Tuples = [tuple()]
Creates a relation [page 215]. relation(R, T) is equivalent to from_term(R, T), if T is a type [page 217] and the result is a relation. If Type is an integer N, then [{atom, ..., atom}]), where the size of the tuple is N, is used as type of the relation.
If no type is explicitly given, the size of the first tuple of Tuples is used if there is such a tuple. relation([]) is equivalent to relation([], 2).

relation_to_family(BinRel) -> Family
Types:
• Family = family()
• BinRel = binary_relation()
Returns the family [page 216] Family such that the index set is equal to the domain [page 215] of the binary relation BinRel, and Family[i] is the image [page 215] of the set of i under BinRel.

1> R = sofs:relation([[b,1],[c,2],[c,3]]).
   F = sofs:relation_to_family(R),
   sofs:to_external(F).
   [{b,[1]},{c,[2,3]}]

relative_product(TupleOfBinRels [, BinRel1]) -> BinRel2

Types:
- TupleOfBinRels = tuple-of(BinRel)
- BinRel = BinRel1 = BinRel2 = binary_relation()

If TupleOfBinRels is a non-empty tuple \{R[1], ..., R[n]\} of binary relations and BinRel1 is a binary relation, then BinRel2 is the relative product [page 216] of the ordered set \{R[i], ..., R[n]\} and BinRel1.

If BinRel1 is omitted, the relation of equality between the elements of the Cartesian product [page 216] of the ranges of R[i], range R[1] × ... × range R[n], is used instead (intuitively, nothing is “lost”).

1> TR = sofs:relation([[1,a],[1,aa],[2,b]]).
   R1 = sofs:relation([[1,u],[2,v],[3,c]]),
   R2 = sofs:relative_product([TR, R1]),
   sofs:to_external(R2).
   [{1,[a,u]},{1,[aa,u]},{2,[b,v]}]

Note that relative_product([R1, R2]) is different from relative_product(R1, R2); the tuple of one element is not identified with the element itself.

relative_product(BinRel1, BinRel2) -> BinRel3

Types:
- BinRel1 = BinRel2 = BinRel3 = binary_relation()

Returns the relative product [page 215] of the binary relations BinRel1 and BinRel2.

relative_product1(BinRel1, BinRel2) -> BinRel3

Types:
- BinRel1 = BinRel2 = BinRel3 = binary_relation()

Returns the relative product [page 215] of the converse [page 215] of the binary relation BinRel1 and the binary relation BinRel2; relative_product1(R1, R2) is equivalent to relative_product(converse(R1), R2), but is more efficient.

1> R1 = sofs:relation([[1,a],[1,aa],[2,b]]),
   R2 = sofs:relation([[1,u],[2,v],[3,c]]),
   R3 = sofs:relative_product1(R1, R2),
   sofs:to_external(R3).
   [{a,u},{aa,u},{b,v}]

restriction(BinRel1, Set) -> BinRel2
Types:
- BinRel1 = BinRel2 = binary_relation()
- Set = set()

Returns the restriction [page 215] of the binary relation BinRel1 to Set.

```prolog
1> R1 = sofs:relation([[1,a],[2,b],[3,c]]),
   S = sofs:set([1,2,4]),
   R2 = sofs:restriction(R1, S),
   sofs:to_external(R2),
   [[1,a],[2,b]]
```

restriction(SetFun, Set1, Set2) -> Set3

Types:
- SetFun = set_fun()
- Set1 = Set2 = Set3 = set()

Returns a subset of Set1 containing those elements that yield an element in Set2 as the result of applying SetFun.

```prolog
1> S1 = sofs:relation([[1,a],[2,b],[3,c]]),
   S2 = sofs:set([b,c,d]),
   S3 = sofs:restriction(2, S1, S2),
   sofs:to_external(S3),
   [[2,b],[3,c]]
```

set(Terms [, Type]) -> Set

Types:
- Set = set()
- Terms = [term()]
- Type = type()

Creates an unordered set [page 217]. set(L, T) is equivalent to from_term(L, T), if the result is an unordered set. If no type [page 217] is explicitly given, [atom] is used as type of the set.

specification(Fun, Set1) -> Set2

Types:
- Fun = spec_fun()
- Set1 = Set2 = set()

Returns the set containing every element of Set1 for which Fun returns true. If Fun is a tuple {external, Fun2}, Fun2 is applied to the external set [page 217] of each element, otherwise Fun is applied to each element.

```prolog
1> R1 = sofs:relation([[a,1],[b,2]]),
   R2 = sofs:relation([[x,1],[x,2],[y,3]]),
   S1 = sofs:from_sets([R1,R2]),
   S2 = sofs:specification({sofs,is_a_function}, S1),
   sofs:to_external(S2),
   [[[a,1],[b,2]]]
```
strict_relation(BinRel1) -> BinRel2

Types:
- BinRel1 = BinRel2 = binary_relation()

Returns the strict relation [page 216] corresponding to the binary relation BinRel1.

1> R1 = sofs:relation([[1,1],[1,2],[2,1],[2,2]]),
   R2 = sofs:strict_relation(R1),
   sofs:to_external(R2),
   [{1,2},{2,1}]

substitution(SetFun, Set1) -> Set2

Types:
- SetFun = set_fun()
- Set1 = Set2 = set()

Returns a function, the domain of which is Set1. The value of an element of the domain is the result of applying SetFun to the element.

1> L = [[a,1],[b,2]].
   [{a,1},{b,2}]
2> sofs:to_external(sofs:projection(1,sofs:relation(L))).
   [a,b]
3> sofs:to_external(sofs:substitution(1,sofs:relation(L))).
   [{a,1,a},{b,2,b}]
4> SetFun = {external, fun({A,_}=E) -> {E,A} end},
   sofs:to_external(sofs:projection(SetFun,sofs:relation(L))).
   [{a,1,a},{b,2,b}]

The relation of equality between the elements of {a,b,c}:

1> I = sofs:substitution(fun(A) -> A end, sofs:set([a,b,c])),
   sofs:to_external(I).
   [{a,a},{b,b},{c,c}]

Let SetOfSets be a set of sets and BinRel a binary relation. The function that maps each element Set of SetOfSets onto the image [page 215] of Set under BinRel is returned by this function:

images(SetOfSets, BinRel) ->
   Fun = fun(Set) -> sofs:image(BinRel, Set) end,
   sofs:substitution(Fun, SetOfSets).

Here might be the place to reveal something that was more or less stated before, namely that external unordered sets are represented as sorted lists. As a consequence, creating the image of a set under a relation R may traverse all elements of R (to that comes the sorting of results, the image). In images/2, BinRel will be traversed once for each element of SetOfSets, which may take too long. The following efficient function could be used instead, assuming that SetOfSets does not contain an empty set and that BinRel is non-empty:

images2(SetOfSets, BinRel) ->
   CR = sofs:canonical_relation(SetOfSets),
   R = sofs:relative_product1(CR, BinRel),
   sofs:relation_to_family(R).
symdiff(Set1, Set2) -> Set3

Types:
- Set1 = Set2 = Set3 = set()

Returns the symmetric difference [page 215] (or the Boolean sum) of Set1 and Set2.

```erlang
1> S1 = sofs:set([1,2,3]),
   S2 = sofs:set([2,3,4]),
   P = sofs:symdiff(S1, S2),
   sofs:to_external(P).
[1,4]
```

symmetric_partition(Set1, Set2) -> {Set3, Set4, Set5}

Types:
- Set1 = Set2 = Set3 = Set4 = Set5 = set()

Returns a triple of three sets: Set3 contains the elements of Set1 that do not belong to Set2; Set4 contains the elements of Set1 that belong to Set2; Set5 contains the elements of Set2 that do not belong to Set1.

to_external(AnySet) -> ExternalSet

Types:
- ExternalSet = external_set()
- AnySet = anyset()

Returns the external set [page 217] of an atomic, ordered or unordered set.

to_sets(ASet) -> Sets

Types:
- ASet = set() | ordset()
- Sets = tuple_of(A nySet) | [AnySet]

Returns the elements of the ordered set ASet as a tuple of sets, and the elements of the unordered set ASet as a sorted list of sets without duplicates.

type(AnySet) -> Type

Types:
- AnySet = anyset()
- Type = type()

Returns the type [page 217] of an atomic, ordered or unordered set.

union(SetOfSets) -> Set

Types:
- Set = set() | ordset()
- SetOfSets = set_of_sets()

Returns the union [page 215] of the set of sets SetOfSets.

union(Set1, Set2) -> Set3
Types:
- Set1 = Set2 = Set3 = set()

Returns the union [page 215] of Set1 and Set2.

union_of_family(Family) -> Set

Types:
- Family = family()
- Set = set()

Returns the union of the family [page 216] Family.

1> F = sofs:family([[a, [0, 2, 4]], [b, [0, 1, 2]], [c, [2, 3]]]),
   S = sofs:union_of_family(F),
   sofs:to_external(S).
   [0, 1, 2, 3, 4]

weak_relation(BinRel1) -> BinRel2

Types:
- BinRel1 = BinRel2 = binary_relation()

Returns a subset S of the weak relation [page 216] W corresponding to the binary relation BinRel1. Let F be the field [page 215] of BinRel1. The subset S is defined so that x S y if x W y for some x in F and for some y in F.

1> R1 = sofs:relation([[1, 1], [1, 2], [3, 1]]),
   R2 = sofs:weak_relation(R1),
   sofs:to_external(R2).
   [[1, 1], [1, 2], [2, 2], [3, 1], [3, 3]]

string

Erlang Module

This module contains functions for string processing.

Exports

len(String) -> Length

Types:
- String = string()
- Length = integer()

Returns the number of characters in the string.

equal(String1, String2) -> bool()

Types:
- String1 = String2 = string()

Tests whether two strings are equal. Returns true if they are, otherwise false.

concat(String1, String2) -> String3

Types:
- String1 = String2 = String3 = string()

Concatenates two strings to form a new string. Returns the new string.

chr(String, Character) -> Index
rchr(String, Character) -> Index

Types:
- String = string()
- Character = char()
- Index = integer()

Returns the index of the first/last occurrence of Character in String. 0 is returned if Character does not occur.

str(String, SubString) -> Index
rstr(String, SubString) -> Index

Types:
- String = SubString = string()
- **Index = integer()**

  Returns the position where the first/last occurrence of SubString begins in String. 0 is returned if SubString does not exist in String. For example:

  > string:str(" Hello Hello World World ", "Hello World").

  8

**span(String, Chars) -> Length**

**cspan(String, Chars) -> Length**

Types:
- **String = Chars = string()**
- **Length = integer()**

Returns the length of the maximum initial segment of String, which consists entirely of characters from (not from) Chars.

For example:

  > string:span("\t abcdef", " \t").

  5

  > string:cspan("\t abcdef", " \t").

  0

**substr(String, Start) -> SubString**

**substr(String, Start, Length) -> Substring**

Types:
- **String = SubString = string()**
- **Start = Length = integer()**

Returns a substring of String, starting at the position Start, and ending at the end of the string or at length Length.

For example:

  > substr("Hello World", 4, 5).

  "lo Wo"

**tokens(String, SeparatorList) -> Tokens**

Types:
- **String = SeparatorList = string()**
- **Tokens = [string()]**

Returns a list of tokens in String, separated by the characters in SeparatorList.

For example:

  > tokens("abc defxxghix jkl", "x ").

  ["abc", "def", "ghi", "jkl"]

**chars(Character, Number) -> String**

**chars(Character, Number, Tail) -> String**

Types:
- **Character = char()**
• Number = integer()
• String = string()

Returns a string consisting of Number of characters Character. Optionally, the string can end with the string Tail.

copies(String, Number) -> Copies

Types:
• String = Copies = string()
• Number = integer()

Returns a string containing String repeated Number times.

words(String) -> Count

words(String, Character) -> Count

Types:
• String = string()
• Character = char()
• Count = integer()

Returns the number of words in String, separated by blanks or Character.

For example:
> words(" Hello old boy!", $o).
4

sub_word(String, Number) -> Word

sub_word(String, Number, Character) -> Word

Types:
• String = Word = string()
• Character = char()
• Number = integer()

Returns the word in position Number of String. Words are separated by blanks or Characters.

For example:
> string:sub_word(" Hello old boy !",3,$o).
"ld b"

strip(String) -> Stripped

strip(String, Direction) -> Stripped

strip(String, Direction, Character) -> Stripped

Types:
• String = Stripped = string()
• Direction = left | right | both
• Character = char()
Returns a string, where leading and/or trailing blanks or a number of Character have been removed. Direction can be left, right, or both and indicates from which direction blanks are to be removed. The function `strip/1` is equivalent to `strip(String, both).

For example:

```
> string:strip("...Hello.....", both, $).
"Hello"
```

**left(String, Number) -> Left**

**left(String, Number, Character) -> Left**

Types:
- String = Left = string()
- Character = char
- Number = integer()

Returns the String with the length adjusted in accordance with Number. The left margin is fixed. If the length(String) < Number, String is padded with blanks or Characters.

For example:

```
> string:left("Hello",10,$).
"Hello....."
```

**right(String, Number) -> Right**

**right(String, Number, Character) -> Right**

Types:
- String = Right = string()
- Character = char
- Number = integer()

Returns the String with the length adjusted in accordance with Number. The right margin is fixed. If the length(String) < Number, String is padded with blanks or Characters.

For example:

```
> string:right("Hello", 10, $).
".....Hello"
```

**centre(String, Number) -> Centered**

**centre(String, Number, Character) -> Centered**

Types:
- String = Centered = string()
- Character = char
- Number = integer()

Returns a string, where String is centred in the string and surrounded by blanks or characters. The resulting string will have the length Number.

**sub_string(String, Start) -> SubString**
sub_string(String, Start, Stop) -> SubString

Types:
- String = SubString = string()
- Start = Stop = integer()

Returns a substring of String, starting at the position Start to the end of the string, or to and including the Stop position.

For example:
sub_string("Hello World", 4, 8).
"lo Wo"

Notes

Some of the general string functions may seem to overlap each other. The reason for this is that this string package is the combination of two earlier packages and all the functions of both packages have been retained.

The regular expression functions have been moved to their own module regexp (see regexp [page 196]). The old entry points still exist for backwards compatibility, but will be removed in a future release so that users are encouraged to use the module regexp.

Note:
Any undocumented functions in string should not be used.
supervisor

Erlang Module

A behaviour module for implementing a supervisor, a process which supervises other processes called child processes. A child process can either be another supervisor or a worker process. Worker processes are normally implemented using one of the gen_event, gen_fsm, or gen_server behaviours. A supervisor implemented using this module will have a standard set of interface functions and include functionality for tracing and error reporting. Supervisors are used to build an hierarchical process structure called a supervision tree, a nice way to structure a fault tolerant application. Refer to OTP Design Principles for more information.

A supervisor assumes the definition of which child processes to supervise to be located in a callback module exporting a pre-defined set of functions.

Unless otherwise stated, all functions in this module will fail if the specified supervisor does not exist or if bad arguments are given.

Supervision Principles

The supervisor is responsible for starting, stopping and monitoring its child processes. The basic idea of a supervisor is that it should keep its child processes alive by restarting them when necessary.

The children of a supervisor is defined as a list of child specifications. When the supervisor is started, the child processes are started in order from left to right according to this list. When the supervisor terminates, it first terminates its child processes in reversed start order, from right to left.

A supervisor can have one of the following restart strategies:

- **one_for_one** - if one child process terminates and should be restarted, only that child process is affected.
- **one_for_all** - if one child process terminates and should be restarted, all other child processes are terminated and then all child processes are restarted.
- **rest_for_one** - if one child process terminates and should be restarted, the 'rest' of the child processes - i.e. the child processes after the terminated child process in the start order - are terminated. Then the terminated child process and all child processes after it are restarted.
- **simple_one_for_one** - a simplified one_for_one supervisor, where all child processes are dynamically added instances of the same process type, i.e. running the same code.

The functions terminate_child/2, delete_child/2 and restart_child/2 are invalid for simple_one_for_one supervisors and will return {error, simple_one_for_one} if the specified supervisor uses this restart strategy.
To prevent a supervisor from getting into an infinite loop of child process terminations and restarts, a maximum restart frequency is defined using two integer values MaxR and MaxT. If more than MaxR restarts occur within MaxT seconds, the supervisor terminates all child processes and then itself.

This is the type definition of a child specification:

```
child_spec() = {Id,StartFunc,Restart,Shutdown,Type,Modules}
  Id = term()
  StartFunc = {M,F,A}
    M = F = atom()
    A = [term()]
  Restart = permanent | transient | temporary
  Shutdown = brutal_kill | int()>=0 | infinity
  Type = worker | supervisor
  Modules = [Module] | dynamic
    Module = atom()
```

- `Id` is a name that is used to identify the child specification internally by the supervisor.
- `StartFunc` defines the function call used to start the child process. It should be a module-function-arguments tuple \( \{M,F,A\} \) used as `apply(M,F,A)`.

The start function must create and link to the child process, and should return \( \{ok,Child\} \) or \( \{ok,Child,Info\} \) where `Child` is the pid of the child process and `Info` an arbitrary term which is ignored by the supervisor.

The start function can also return `ignore` if the child process for some reason cannot be started, in which case the child specification will be kept by the supervisor but the non-existing child process will be ignored.

If something goes wrong, the function may also return an error tuple \( \{error,Error\} \).

Note that the `start_link` functions of the different behaviour modules fulfill the above requirements.

- `Restart` defines when a terminated child process should be restarted. A permanent child process should always be restarted, a temporary child process should never be restarted and a transient child process should be restarted only if it terminates abnormally, i.e. with another exit reason than normal.
- `Shutdown` defines how a child process should be terminated. `brutal_kill` means the child process will be unconditionally terminated using `exit(Child,killed)`. An integer timeout value means that the supervisor will tell the child process to terminate by calling `exit(Child,shutdown)` and then wait for an exit signal from the child process. If no exit signal is received within the specified time, the child process is unconditionally terminated using `exit(Child,killed)`.
  If the child process is another supervisor, `Shutdown` should be set to `infinity` to give the subtree ample time to shutdown.
- `Type` specifies if the child process is a supervisor or a worker.
The supervisor module is used by the release handler during code replacement to determine which processes are using a certain module. As a rule of thumb, Modules should be a list with one element `[Module]`, where Module is the name of the callback module, if the child process is a supervisor, gen_server or gen_fsm. If the child process is an event manager (gen_event) with a dynamic set of callback modules, Modules should be dynamic. See SASL User's Guide for more information.

Internally, the supervisor also keeps track of the pid Child of the child process, or undefined if no pid exists.

Exports

```erlang
start_link(Module, Args) -> Result
start_link(SupName, Module, Args) -> Result
```

Types:
- `SupName = {local,Name} | {global,Name}`
- `ModuleName = atom()`
- `ModuleName = atom()`
- `Args = term()`
- `Result = {ok,Pid} | ignore | {error,Error}`
- `Pid = pid()`
- `Error = {already_started,Pid} | shutdown | term()`

Creates a supervisor process, linked to the calling process, which calls Module:init/1 to find out about restart strategy, maximum restart frequency and child processes. To ensure a synchronized start-up procedure, this function does not return until Module:init/1 has returned and all child processes have been started.

If SupName={local,Name} the supervisor is registered locally as Name using register/2. If SupName={global,Name} the supervisor is registered globally as Name using global:register_name/2. If no name is provided, the supervisor is not registered. If there already exists a process with the specified SupName the function returns `{error,[already_started,Pid]}`, where Pid is the pid of that process.

Module is the name of the callback module.

Args is an arbitrary term which is passed as the argument to Module:init/1.

If the supervisor and its child processes are successfully created (i.e. if all child process start functions return `{ok,Child}, `{ok,Child,Info}, or ignore) the function returns `{ok,Pid}`, where Pid is the pid of the supervisor.

If Module:init/1 returns ignore, this function returns ignore as well and the supervisor terminates with reason normal. If Module:init/1 fails or returns an incorrect value, this function returns `{error,Term}` where Term is a term with information about the error, and the supervisor terminates with reason Term.

If any child process start function fails or returns an error tuple or an erroneous value, the function returns `{error,shutdown}` and the supervisor terminates all started child processes and then itself with reason shutdown.

```erlang
start_child(SupRef, ChildSpec) -> Result
```

Types:
Dynamically adds a child specification to the supervisor \( SupRef \) which starts the corresponding child process.

\( SupRef \) can be:

- the pid,
- \( Name \), if the supervisor is locally registered,
- \( \{Name,Node\} \), if the supervisor is locally registered at another node, or
- \( \{global,Name\} \), if the supervisor is globally registered.

\( ChildSpec \) should be a valid child specification (unless the supervisor is a simple_one_for_one supervisor, see below). The child process will be started by using the start function as defined in the child specification.

If the case of a simple_one_for_one supervisor, the child specification defined in Module: init/1 will be used and \( ChildSpec \) should instead be an arbitrary list of terms \( List \). The child process will then be started by appending \( List \) to the existing start function arguments, i.e. by calling \( \text{apply}(M, F, A+List) \) where \( \{M,F,A\} \) is the start function defined in the child specification.

If there already exists a child specification with the specified \( Id \), \( ChildSpec \) is discarded and the function returns \{error, already_present \} or \{error, \{already_started,Child\} \}, depending on if the corresponding child process is running or not.

If the child process start function returns \{ok,Child\} or \{ok,Child,Info\}, the child specification and pid is added to the supervisor and the function returns the same value.

If the child process start function returns ignore, the child specification is added to the supervisor, the pid is set to undefined and the function returns \{ok,undefined\}.

If the child process start function returns an error tuple or an erroneous value, or if it fails, the child specification is discarded and the function returns \{error,Error\} where \( Error \) is a term containing information about the error and child specification.

terminate_child(SupRef, Id) -> Result

Types:

- \( SupRef = Name \mid \{Name,Node\} \mid \{global,Name\} \mid \text{pid}() \)
- \( Name = Node = \text{atom}() \)
- \( Id = \text{term}() \)
- \( Result = \text{ok} \mid \{\text{error}, Error\} \)
- \( Error = \text{not_found} \mid \text{simple_one_for_one} \)
Tells the supervisor \texttt{SupRef} to terminate the child process corresponding to the child specification identified by \texttt{Id}. The process, if there is one, is terminated but the child specification is kept by the supervisor. This means that the child process may be later be restarted by the supervisor. The child process can also be restarted explicitly by calling \texttt{restart\_child/2}. Use \texttt{delete\_child/2} to remove the child specification.

See \texttt{start\_child/2} for a description of \texttt{SupRef}.

If successful, the function returns \texttt{ok}. If there is no child specification with the specified \texttt{Id}, the function returns \{error,not\_found\}.

\texttt{delete\_child(SupRef, Id) -> Result}

Types:
\begin{itemize}
  \item \texttt{SupRef} = \texttt{Name} | \{\texttt{Name},\texttt{Node}\} | \{\texttt{global},\texttt{Name}\} | \texttt{pid()}
  \item \texttt{Name} = \texttt{Node} = \texttt{atom()}
  \item \texttt{Id} = \texttt{term()}
  \item \texttt{Result} = \texttt{ok} | \texttt{error,Error}
  \item \texttt{Error} = \texttt{running} | \texttt{not\_found} | \texttt{simple\_one\_for\_one}
\end{itemize}

Tells the supervisor \texttt{SupRef} to delete the child specification identified by \texttt{Id}. The corresponding child process must not be running, use \texttt{terminate\_child/2} to terminate it.

See \texttt{start\_child/2} for a description of \texttt{SupRef}.

If successful, the function returns \texttt{ok}. If the child specification identified by \texttt{Id} exists but the corresponding child process is running, the function returns \{error,running\}. If the child specification identified by \texttt{Id} does not exist, the function returns \{error,not\_found\}.

\texttt{restart\_child(SupRef, Id) -> Result}

Types:
\begin{itemize}
  \item \texttt{SupRef} = \texttt{Name} | \{\texttt{Name},\texttt{Node}\} | \{\texttt{global},\texttt{Name}\} | \texttt{pid()}
  \item \texttt{Name} = \texttt{Node} = \texttt{atom()}
  \item \texttt{Id} = \texttt{term()}
  \item \texttt{Result} = \{\texttt{ok,Child}\} | \{\texttt{ok,Child,Info}\} | \texttt{error,Error}
  \item \texttt{Child} = \texttt{pid()} | \texttt{undefined}
  \item \texttt{Error} = \texttt{running} | \texttt{not\_found} | \texttt{simple\_one\_for\_one} | \texttt{term()}
\end{itemize}

Tells the supervisor \texttt{SupRef} to restart a child process corresponding to the child specification identified by \texttt{Id}. The child specification must exist and the corresponding child process must not be running.

See \texttt{start\_child/2} for a description of \texttt{SupRef}.

If the child specification identified by \texttt{Id} does not exist, the function returns \{error,not\_found\}. If the child specification exists but the corresponding process is already running, the function returns \{error,running\}.

If the child process start function returns \{\texttt{ok,Child}\} or \{\texttt{ok,Child,Info}\}, the pid is added to the supervisor and the function returns the same value.

If the child process start function returns \texttt{ignore}, the pid remains set to \texttt{undefined} and the function returns \{\texttt{ok,undefined}\}. 
If the child process start function returns an error tuple or an erroneous value, or if it fails, the function returns {error, Error} where Error is a term containing information about the error.

which_children(SupRef) -> [{Id, Child, Type, Modules}]

Types:
- SupRef = Name | {Name, Node} | {global, Name} | pid()
- Name = Node = atom()
- Id = term() | undefined
- Child = pid() | undefined
- Type = worker | supervisor
- Modules = [Module] | dynamic
- Module = atom()

Returns a list with information about all child specifications and child processes belonging to the supervisor SupRef. See start_child/2 for a description of SupRef.

The information given for each child specification/process is:

- Id - as defined in the child specification or undefined in the case of a simple one_for_one supervisor.
- Child - the pid of the corresponding child process, or undefined if there is no such process.
- Type - as defined in the child specification.
- Modules - as defined in the child specification.

check_childspecs([ChildSpec]) -> Result

Types:
- ChildSpec = child_spec()
- Result = ok | {error, Error}
- Error = term()

This function takes a list of child specification as argument and returns ok if all of them are syntactically correct, or {error, Error} otherwise.

CALLBACK FUNCTIONS

The following functions should be exported from a supervisor callback module.
Exports

Module:init(Args) -> Result

Types:
- Args = term()
- Result = {ok,{{RestartStrategy,MaxR,MaxT},[ChildSpec]}} | ignore
- RestartStrategy = one_for_all | one_for_one | rest_for_one | simple_one_for_one
- MaxR = MaxT = int() = 0
- ChildSpec = child_spec()

Whenever a supervisor is started using supervisor:start_link/2,3, this function is called by the new process to find out about restart strategy, maximum restart frequency and child specifications.

Args is the Args argument provided to the start function.

RestartStrategy is the restart strategy and MaxR and MaxT defines the maximum restart frequency of the supervisor. [ChildSpec] is a list of valid child specifications defining which child processes the supervisor should start and monitor. See the discussion about Supervision Principles above.

Note that when the restart strategy is simple_one_for_one, the list of child specifications must be a list with one child specification only. (The Id is ignored). No child process is then started during the initialization phase, but all children are assumed to be started dynamically using supervisor:start_child/2.

The function may also return ignore.

SEE ALSO

gen_event(3), gen_fsm(3), gen_server(3), sys(3)
supervisor_bridge

Erlang Module

A behaviour module for implementing a supervisor_bridge, a process which connects a subsystem not designed according to the OTP design principles to a supervision tree. The supervisor_bridge sits between a supervisor and the subsystem. It behaves like a real supervisor to its own supervisor, but has a different interface than a real supervisor to the subsystem. Refer to OTP Design Principles for more information.

A supervisor_bridge assumes the functions for starting and stopping the subsystem to be located in a callback module exporting a pre-defined set of functions. The sys module can be used for debugging a supervisor_bridge.

Unless otherwise stated, all functions in this module will fail if the specified supervisor_bridge does not exist or if bad arguments are given.

Exports

start_link(Module, Args) -> Result
start_link(SupBridgeName, Module, Args) -> Result

Types:
- SupBridgeName = {local, Name} | {global, Name}
- Name = atom()
- Module = atom()
- Args = term()
- Result = {ok, Pid} | ignore | {error, Error}
- Pid = pid()
- Error = {already_started, Pid} | term()

Creates a supervisor_bridge process, linked to the calling process, which calls Module:init/1 to start the subsystem. To ensure a synchronized start-up procedure, this function does not return until Module:init/1 has returned.

If SupBridgeName={local, Name} the supervisor_bridge is registered locally as Name using register/2. If SupBridgeName={global, Name} the supervisor_bridge is registered globally as Name using global:register_name/2. If no name is provided, the supervisor_bridge is not registered. If there already exists a process with the specified SupBridgeName the function returns {error, {already_started, Pid}}, where Pid is the pid of that process.

Module is the name of the callback module.

Args is an arbitrary term which is passed as the argument to Module:init/1.

If the supervisor_bridge and the subsystem are successfully started the function returns {ok, Pid}, where Pid is the pid of the supervisor_bridge.
If `Module:init/1` returns `ignore`, this function returns `ignore` as well and the `supervisor_bridge` terminates with reason `normal`. If `Module:init/1` fails or returns an error tuple or an incorrect value, this function returns `{error,Term}` where `Term` is a term with information about the error, and the `supervisor_bridge` terminates with reason `Term`.

**CALLBACK FUNCTIONS**

The following functions should be exported from a `supervisor_bridge` callback module.

**Exports**

### `Module:init(Arg)`

- **Types**:
  - `Arg` = `term`()
  - `Result` = `ok`, `Pid`, `State` | `ignore` | `{error,Error}`
  - `Pid` = `pid`()
  - `State` = `term`()
  - `Error` = `term`()

Whenever a `supervisor_bridge` is started using `supervisor_bridge:start_link/2,3`, this function is called by the new process to start the subsystem and initialize. `Arg` is the `Arg` argument provided to the start function.

The function should return `{ok,Pid,State}` where `Pid` is the pid of the main process in the subsystem and `State` is any term.

If later `Pid` terminates with a reason `Reason`, the `supervisor_bridge` will terminate with reason `Reason` as well. If later the `supervisor_bridge` is stopped by its supervisor with reason `Reason`, it will call `Module:terminate(Reason,State)` to terminate.

If something goes wrong during the initialization the function should return `{error,Error}` where `Error` is any term, or `ignore`.

### `Module:terminate(Reason, State)`

- **Types**:
  - `Reason` = `shutdown` | `term`()
  - `State` = `term`()

This function is called by the `supervisor_bridge` when it is about to terminate. It should be the opposite of `Module:init/1` and stop the subsystem and do any necessary cleaning up. The return value is ignored.

`Reason` is `shutdown` if the `supervisor_bridge` is terminated by its supervisor. If the `supervisor_bridge` terminates because a a linked process (apart from the main process of the subsystem) has terminated with reason `Term`, `Reason` will be `Term`.

`State` is taken from the return value of `Module:init/1`. 
SEE ALSO

supervisor(3), sys(3)
**SYS**

Erlang Module

This module contains functions for sending system messages used by programs, and messages used for debugging purposes.

Functions used for implementation of processes should also understand system messages such as debugging messages and code change. These functions must be used to implement the use of system messages for a process, either directly, or through standard behaviours, such as `gen_server`.

The following types are used in the functions defined below:

- **Name** = `pid()` | `atom()` | `{global, atom()}`
- **Timeout** = `int()` >= 0 | `infinity`
- **system_event()** = `{in, Msg}` | `{in, Msg, From}` | `{out, Msg, To}` | `term()`

The default timeout is 5000 ms, unless otherwise specified. The `timeout` defines the time period to wait for the process to respond to a request. If the process does not respond, the function evaluates `exit([timeout, {M, F, A}]).`

The functions make reference to a debug structure. The debug structure is a list of `dbg opt()`. `dbg opt()` is an internal data type used by the `handle_system_msg/6` function. No debugging is performed if it is an empty list.

**System Messages**

Processes which are not implemented as one of the standard behaviours must still understand system messages. There are three different messages which must be understood:

- **Plain system messages.** These are received as `{system, From, Msg}. The content and meaning of this message are not interpreted by the receiving process module. When a system message has been received, the function `sys:handle_system_msg/6` is called in order to handle the request.

- **Shutdown messages.** If the process traps exits, it must be able to handle a shut-down request from its parent, the supervisor. The message `{EXIT', Parent, Reason}` from the parent is an order to terminate. The process must terminate when this message is received, normally with the same Reason as Parent.
• There is one more message which the process must understand if the modules used to implement the process change dynamically during runtime. An example of such a process is the gen_event processes. This message is {get_modules, From}. The reply to this message is From ! {modules, Modules}, where Modules is a list of the currently active modules in the process. This message is used by the release handler to find which processes execute a certain module. The process may at a later time be suspended and ordered to perform a code change for one of its modules.

System Events

When debugging a process with the functions of this module, the process generates system_events which are then treated in the debug function. For example, trace formats the system events to the tty. There are three predefined system events which are used when a process receives or sends a message. The process can also define its own system events. It is always up to the process itself to format these events.

Exports

log(Name, Flag)
log(Name, Flag, Timeout) → ok | {ok, [system_event()]} Types:
• Flag = true | {true, N} | false | get | print
• N = integer() > 0

Turns the logging of system events On or Off. If On, a maximum of N events are kept in the debug structure (the default is 10). If Flag is get, a list of all logged events is returned. If Flag is print, the logged events are printed to standard io. The events are formatted with a function that is defined by the process that generated the event (with a call to sys:handle_debug/4).

log_to_file(Name, Flag)
log_to_file(Name, Flag, Timeout) → ok | {error, open_file}
Types:
• Flag = FileName | false
• FileName = string()

Enables or disables the logging of all system events in textual format to the file. The events are formatted with a function that is defined by the process that generated the event (with a call to sys:handle_debug/4).

statistics(Name, Flag)
statistics(Name, Flag, Timeout) → ok | {ok, Statistics}
Types:
• Flag = true | false | get
Statistics = Start time, Date1, Time1, Current time, Date2, Time2, Reductions, Integer(), Messages in, Integer(), Messages out, Integer()

Date1 = Date2 = Year, Month, Day

Time1 = Time2 = Hour, Min, Sec

Enables or disables the collection of statistics. If Flag is get, the statistical collection is returned.

trace(Name, Flag)
trace(Name, Flag, Timeout) -> void()

Types:
- Flag = boolean()

Prints all system events on standard io. The events are formatted with a function that is defined by the process that generated the event (with a call to sys:handle debug/4).

no_debug(Name)
no_debug(Name, Timeout) -> void()

Turns off all debugging for the process. This includes functions that have been installed explicitly with the install function, for example triggers.

suspend(Name)
suspend(Name, Timeout) -> void()

Suspends the process. When the process is suspended, it will only respond to other system messages, but not other messages.

resume(Name)
resume(Name, Timeout) -> void()

Resumes a suspended process.

change_code(Name, Module, OldVsn, Extra)
change_code(Name, Module, OldVsn, Extra, Timeout) -> ok | {error, Reason}

Types:
- OldVsn = undefined | term()
- Module = atom()
- Extra = term()

Tells the process to change code. The process must be suspended to handle this message. The Extra argument is reserved for each process to use as its own. The function Mod:system code change/4 is called. OldVsn is the old version of the Module.

get_status(Name)
gestatus(Name, Timeout) -> {status, Pid, {module, Mod}, [{PDict, SysState, Parent, Dbg, Misc}]

Types:
- PDict = [{Key, Value}]
- SysState = running | suspended
- Parent = pid()}
• Dbg = {dbg_opt()}
  Misc = term()

Gets the status of the process.

install(Name, {Func, FuncState})
install(Name, {Func, FuncState}, Timeout)

Types:
• Func = dbg_fun()
  dbg_fun() = fun(FuncState, Event, ProcState) -\> done | NewFuncState
  FuncState = term()
  Event = system_event()
  ProcState = term()
  NewFuncState = term()

This function makes it possible to install other debug functions than the ones defined
above. An example of such a function is a trigger, a function that waits for some special
event and performs some action when the event is generated. This could, for example,
be turning on low level tracing.

Func is called whenever a system event is generated. This function should return done,
or a new func state. In the first case, the function is removed. It is removed if the
function fails.

remove(Name, Func)
remove(Name, Func, Timeout) -\> void()

Types:
• Func = dbg_fun()

Removes a previously installed debug function from the process. Func must be the same
as previously installed.

Process Implementation Functions

The following functions are used when implementing a special process. This is an
ordinary process which does not use a standard behaviour, but a process which
understands the standard system messages.
Exports

debug_options(Options) -> [dbg_opt()]

Types:
- Options = [Opt]
- Opt = trace | log | statistics | {log_to_file, FileName} | {install, {Func, FuncState}}
- Func = dbg_fun()
- FuncState = term()

This function can be used by a process that initiates a debug structure from a list of options. The values of the Opt argument are the same as the corresponding functions.

get_debug(Item, Debug, Default) -> term()

Types:
- Item = log | statistics
- Debug = [dbg_opt()]
- Default = term()

This function gets the data associated with a debug option. Default is returned if the Item is not found. Can be used by the process to retrieve debug data for printing before it terminates.

handle_debug([dbg_opt()], FormFunc, Extra, Event) -> [dbg_opt()]

Types:
- FormFunc = dbg_fun()
- Extra = term()
- Event = system_event()

This function is called by a process when it generates a system event. FormFunc is a formatting function which is called as FormFunc(Device, Event, Extra) in order to print the events, which is necessary if tracing is activated. Extra is any extra information which the process needs in the format function, for example the name of the process.

handle_system_msg(Msg, From, Parent, Module, Debug, Misc)

Types:
- Msg = term()
- From = pid()
- Parent = pid()
- Module = atom()
- Debug = [dbg_opt()]
- Misc = term()
This function is used by a process module that wishes to take care of system messages. The process receives a \{system, From, Msg\} message and passes the Msg and From to this function.

This function never returns. It calls the function Mod:system\_continue(Parent, NDebug, Misc) where the process continues the execution, or Mod:system\_terminate(Reason, Parent, Debug, Misc) if the process should terminate. The Module must export system\_continue/3, system\_terminate/4, and system\_code\_change/4 (see below).

The Misc argument can be used to save internal data in a process, for example its state. It is sent to Mod:system\_continue/3 or Mod:system\_terminate/4.

\texttt{print\_log(Debug) \rightarrow void()}

Types:
- \texttt{Debug = [dbg\_opt()]} 

Prints the logged system events in the debug structure using FormFunc as defined when the event was generated by a call to handle\_debug/4.

\textbf{Mod:system\_continue(Parent, Debug, Misc)}

Types:
- \texttt{Parent = pid()}
- \texttt{Debug = [dbg\_opt()]} 
- \texttt{Misc = term()}

This function is called from sys:handle\_system\_msg/6 when the process should continue its execution (for example after it has been suspended). This function never returns.

\textbf{Mod:system\_terminate(Reason, Parent, Debug, Misc)}

Types:
- \texttt{Reason = term()}
- \texttt{Parent = pid()}
- \texttt{Debug = [dbg\_opt()]} 
- \texttt{Misc = term()}

This function is called from sys:handle\_system\_msg/6 when the process should terminate. For example, this function is called when the process is suspended and its parent orders shut-down. It gives the process a chance to do a clean-up. This function never returns.

\textbf{Mod:system\_code\_change(Misc, Module, OldVsn, Extra) \rightarrow \{ok, NMisc\}}

Types:
- \texttt{Misc = term()}
- \texttt{OldVsn = undefined | term()}
- \texttt{Module = atom()}
- \texttt{Extra = term()}
- \texttt{NMisc = term()}
Called from `sys:handle_system_msg/6` when the process should perform a code change. The code change is used when the internal data structure has changed. This function converts the `Misc` argument to the new data structure. `OldVsn` is the `vsn` attribute of the old version of the `Module`. If no such attribute was defined, the atom `undefined` is sent.
This module provides useful functions related to time. Unless otherwise stated, time is always measured in milliseconds. All timer functions return immediately, regardless of work carried out by another process.

Successful evaluations of the timer functions yield return values containing a timer reference, denoted \texttt{TRef} below. By using \texttt{cancel/1}, the returned reference can be used to cancel any requested action. A \texttt{TRef} is an Erlang term, the contents of which must not be altered.

The timeouts are not exact, but should be at least as long as requested.

**Exports**

\texttt{start() -} \texttt{ok}

Starts the timer server. Normally, the server does not need to be started explicitly. It is started dynamically if it is needed. This is useful during development, but in a target system the server should be started explicitly. Use configuration parameters for \texttt{kernel} for this.

\texttt{apply\_after(Time, Module, Function, Arguments) -} \texttt{\{ok, TRef\} | \{error, Reason\}}

Types:
- \texttt{Time = integer() in Milliseconds}
- \texttt{Module = Function = atom()}
- \texttt{Arguments = [term()]}  

Evaluates \texttt{apply(M, F, A) after Time amount of time has elapsed. Returns \{ok, TRef\}, or \{error, Reason\}.}

\texttt{send\_after(Time, Pid, Message) -} \texttt{\{ok, TRef\} | \{error, Reason\}}

\texttt{send\_after(Time, Message) -} \texttt{\{ok, TRef\} | \{error, Reason\}}

Types:
- \texttt{Time = integer() in Milliseconds}
- \texttt{Pid = pid() | atom()}
- \texttt{Message = term()}
- \texttt{Result = \{ok, TRef\} | \{error, Reason\}}

\texttt{send\_after/3} Evaluates \texttt{Pid} ! \texttt{Message} after \texttt{Time} amount of time has elapsed. (\texttt{Pid} can also be an atom of a registered name.) Returns \texttt{\{ok, TRef\}, or \{error, Reason\}.}
send_after/2  Same as send_after(Time, self(), Message).

exit_after(Time, Pid, Reason1) -> {ok, TRef} | {error, Reason2}
exit_after(Time, Reason1) -> {ok, TRef} | {error, Reason2}
kill_after(Time, Pid) -> {ok, TRef} | {error, Reason2}
kill_after(Time) -> {ok, TRef} | {error, Reason2}

Types:
• Time = integer() in milliseconds
• Pid = pid() | atom()
• Reason1 = Reason2 = term()

exit_after/3  Send an exit signal with reason Reason1 to Pid Pid. Returns {ok, TRef}, or {error, Reason2}.
exit_after/2  Same as exit_after(Time, self(), Reason1).
kill_after/2 Same as exit_after(Time, Pid, kill).
kill_after/1 Same as exit_after(Time, self(), kill).

apply_interval(Time, Module, Function, Arguments) -> {ok, TRef} | {error, Reason}

Types:
• Time = integer() in milliseconds
• Module = Function = atom()
• Arguments = [term()]

Evaluates apply(Module, Function, Arguments) repeatedly at intervals of Time. Returns {ok, TRef}, or {error, Reason}.

send_interval(Time, Pid, Message) -> {ok, TRef} | {error, Reason}
send_interval(Time, Message) -> {ok, TRef} | {error, Reason}

Types:
• Time = integer() in milliseconds
• Pid = pid() | atom()
• Message = term()
• Reason = term()

send_interval/3  Evaluates Pid ! Message repeatedly after Time amount of time has elapsed. (Pid can also be an atom of a registered name.) Returns {ok, TRef} or {error, Reason}.
send_interval/2 Same as send_interval(Time, self(), Message).

cancel(TRef) -> {ok, cancel} | {error, Reason}

Cancels a previously requested timeout. TRef is a unique timer reference returned by the timer function in question. Returns {ok, cancel}, or {error, Reason} when TRef is not a timer reference.

sleep(Time) -> ok
Types:
- Time = integer() in milliseconds

Suspends the process calling this function for Time amount of milliseconds and then returns ok. Naturally, this function does not return immediately.

tc(Module, Function, Arguments) -> {Time, Value}

Types:
- Module = Function = atom()
- Arguments = [term()]
- Time = integer() in microseconds
- Value = term()

Evaluates apply(Module, Function, Arguments) and measures the elapsed real time. Returns {Time, Value}, where Time is the elapsed real time in microseconds, and Value is what is returned from the apply.

seconds(Seconds) -> Milliseconds

Returns the number of milliseconds in Seconds.

minutes(Minutes) -> Milliseconds

Return the number of milliseconds in Minutes.

hours(Hours) -> Milliseconds

Returns the number of milliseconds in Hours.

hms(Hours, Minutes, Seconds) -> Milliseconds

Returns the number of milliseconds in Hours + Minutes + Seconds.

Examples

This example illustrates how to print out “Hello World!” in 5 seconds:

```erlang
1> timer:apply_after(5000, io, format, ["~nHello World!~n", []]).
{ok,TRef}
Hello World!
2>
```

The following coding example illustrates a process which performs a certain action and if this action is not completed within a certain limit, then the process is killed.

```erlang
Pid = spawn(mod, fun, [foo, bar]),
%%% If pid is not finished in 10 seconds, kill him
{ok, R} = timer:kill_after(timer:seconds(10), Pid),
...
%%% We change our mind...
timer:cancel(R),
...
WARNING

A timer can always be removed by calling `cancel/1`.

An interval timer, i.e. a timer created by evaluating any of the functions `apply/4`, `send/4`, and `send/3`, is linked to the process towards which the timer performs its task.

A one-shot timer, i.e. a timer created by evaluating any of the functions `apply/4`, `send/4`, `send/3`, `exit/3`, `exit/2`, `kill/2`, and `kill/1` is not linked to any process. Hence, such a timer is removed only when it reaches its timeout, or if it is explicitly removed by a call to `cancel/1`. 
unix

Erlang Module

This module makes it possible to make calls to the UNIX shell. The shell used is /in/sh, so the environment might be different to the one you commonly use. C shell expansions cannot be used. The module is extremely easy to use and there is only one function.

Note that most UNIX commands produce a trailing new line.

Exports

 cmd(String)

Makes the call String to sh and returns the answer in a list of characters.

Example: (bizarre version of ls)

1> unix:cmd("for i in *; do echo $i; done").
win32reg

Erlang Module

**win32reg** provides read and write access to the registry on Windows. It is essentially a port driver wrapped around the Win32 API calls for accessing the registry.

The registry is a hierarchical database, used to store various system and software information in Windows. It is available in Windows 95 and Windows NT. It contains installation data, and is updated by installers and system programs. The Erlang installer updates the registry by adding data that Erlang needs.

The registry contains keys and values. Keys are like the directories in a file system, they form a hierarchy. Values are like files, they have a name and a value, and also a type.

Paths to keys are left to right, with sub-keys to the right and backslash between keys. (Remember that backslashes must be doubled in Erlang strings.) Case is preserved but not significant. Example: 

```
\hkey\local\machine\software\Ericsson\Erlang\5.0
```

is the key for the installation data for the latest Erlang release.

There are six entry points in the Windows registry, top level keys. They can be abbreviated in the win32reg module as:

<table>
<thead>
<tr>
<th>Abbrev.</th>
<th>Registry key</th>
</tr>
</thead>
<tbody>
<tr>
<td>hkr</td>
<td>HKEY_CLASSES_ROOT</td>
</tr>
<tr>
<td>current_user</td>
<td>HKEY_CURRENT_USER</td>
</tr>
<tr>
<td>hcu</td>
<td>HKEY_CURRENT_USER</td>
</tr>
<tr>
<td>local_machine</td>
<td>HKEY_LOCAL_MACHINE</td>
</tr>
<tr>
<td>hklm</td>
<td>HKEY_LOCAL_MACHINE</td>
</tr>
<tr>
<td>users</td>
<td>HKEY_USERS</td>
</tr>
<tr>
<td>hku</td>
<td>HKEY_USERS</td>
</tr>
<tr>
<td>current_config</td>
<td>HKEY_CURRENT_CONFIG</td>
</tr>
<tr>
<td>hkcc</td>
<td>HKEY_CURRENT_CONFIG</td>
</tr>
<tr>
<td>dyn_data</td>
<td>HKEY_DYN_DATA</td>
</tr>
<tr>
<td>hkdd</td>
<td>HKEY_DYN_DATA</td>
</tr>
</tbody>
</table>

The key above could be written as "\hklm\software\ericsson\erlang\5.0".

The win32reg module uses a current key. It works much like the current directory. From the current key, values can be fetched, sub-keys can be listed, and so on.

Under a key, any number of named values can be stored. They have name, and types, and data.

Currently, the win32reg module supports storing only the following types: 
REG_DWORD, which is an integer, REG_SZ which is a string and REG_BINARY which is a binary. Other types can be read, and will be returned as binaries.

There is also a “default” value, which has the empty string as name. It is read and written with the atom default instead of the name.
Some registry values are stored as strings with references to environment variables, e.g. "%SystemRoot%\Windows". SystemRoot is an environment variable, and should be replaced with its value. A function `expand/1` is provided, so that environment variables surrounded in % can be expanded to their values.

For additional information on the Windows registry consult the Win32 Programmer’s Reference.

Exports

`change_key(RegHandle, Key) -> ReturnValue`

Types:
- `RegHandle = term()`
- `Key = string()`

Changes the current key to another key. Works like cd. The key can be specified as a relative path or as an absolute path, starting with \\.

`change_key_create(RegHandle, Key) -> ReturnValue`

Types:
- `RegHandle = term()`
- `Key = string()`

Creates a key, or just changes to it, if it is already there. Works like a combination of `mkdir` and `cd`. Calls the Win32 API function `RegCreateKeyEx()`.

The registry must have been opened in write-mode.

`close(RegHandle) -> ReturnValue`

Types:
- `RegHandle = term()`

Closes the registry. After that, the `RegHandle` cannot be used.

`current_key(RegHandle) -> ReturnValue`

Types:
- `RegHandle = term()`
- `ReturnValue = {ok, string()}`

Returns the path to the current key. This is the equivalent of `pwd`. Note that the current key is stored in the driver, and might be invalid (e.g. if the key has been removed).

`delete_key(RegHandle) -> ReturnValue`

Types:
- `RegHandle = term()`
- `ReturnValue = ok | {error, ErrorId}`
Deletes the current key, if it is valid. Calls the Win32 API function `RegDeleteKey()`. Note that this call does not change the current key, (unlike `change_key/2`.) This means that after the call, the current key is invalid.

```erlang
delete_value(RegHandle, Name) -> ReturnValue
Types:
  • RegHandle = term()
  • ReturnValue = ok | {error, ErrorId}
```

Deletes a named value on the current key. The atom `default` is used for the the default value.

The registry must have been opened in write-mode.

```erlang
expand(String) -> ExpandedString
Types:
  • String = string()
  • ExpandedString = string()
```

Expands a string containing environment variables between percent characters. Anything between two `%` is taken for a environment variable, and is replaced by the value. Two consecutive `%` is replaced by one `%`.

A variable name that is not in the environment, will result in an error.

```erlang
format_error(ErrorId) -> ErrorString
Types:
  • ErrorId = atom()
  • ErrorString = string()
```

Convert an POSIX errorcode to a string (by calling `erl_posix_msg:message`).

```erlang
open(OpenModeList) -> ReturnValue
Types:
  • OpenModeList = [OpenMode]
  • OpenMode = read | write
```

Opens the registry for reading or writing. The current key will be the root (`HKEY_CLASSES_ROOT`). The `read` flag in the mode list can be omitted. Use `change_key/2` with an absolute path after `open`.

```erlang
set_value(RegHandle, Name, Value) -> ReturnValue
Types:
  • Name = string() | default
  • Value = string() | integer() | binary()
```
Sets the named (or default) value to value. Calls the Win32 API function RegSetValueEx(). The value can be of three types, and the corresponding registry type will be used. Currently the types supported are: REG_DWORD for integers, REG_SZ for strings and REG_BINARY for binaries. Other types cannot currently be added or changed. The registry must have been opened in write-mode.

\[
\text{sub\_keys(RegHandle) -> ReturnValue}
\]
\[
\text{Types:}
\]
\[
\begin{itemize}
  \item \text{ReturnValue} = \{\text{ok, SubKeys} \} \mid \{\text{error, ErrorId}\}
  \item \text{SubKeys} = [\text{SubKey}]
  \item \text{SubKey} = \text{string()}
\end{itemize}
\]

Returns a list of subkeys to the current key. Calls the Win32 API function EnumRegKeysEx(). Avoid calling this on the root keys, it can be slow.

\[
\text{value(RegHandle, Name) -> ReturnValue}
\]
\[
\text{Types:}
\]
\[
\begin{itemize}
  \item \text{Name} = \text{string()} \mid \text{default}
  \item \text{ReturnValue} = \{\text{ok, Value}\}
  \item \text{Value} = \text{string()} \mid \text{integer()} \mid \text{binary()}
\end{itemize}
\]

Retrieves the named value (or default) on the current key. Registry values of type REG_SZ, are returned as strings. Type REG_DWORD values are returned as integers. All other types are returned as binaries.

\[
\text{values(RegHandle) -> ReturnValue}
\]
\[
\text{Types:}
\]
\[
\begin{itemize}
  \item \text{ReturnValue} = \{\text{ok, ValuePairs}\}
  \item \text{ValuePairs} = [\text{ValuePair}]
  \item \text{ValuePair} = \{\text{Name, Value}\}
  \item \text{Name} = \text{string()} \mid \text{default}
  \item \text{Value} = \text{string()} \mid \text{integer()} \mid \text{binary()}
\end{itemize}
\]

Retrieves a list of all values on the current key. The values have types corresponding to the registry types, see value. Calls the Win32 API function EnumRegValuesEx().
