STDLIB Reference Manual

Short Summaries

- Erlang Module beam_lib [page 44] – An interface to the BEAM file format
- Erlang Module c [page 48] – Command Interface Module
- Erlang Module calendar [page 53] – Local and universal time, day-of-the-week, date and time conversions
- Erlang Module dets [page 58] – A Disk Based Term Storage
- Erlang Module dict [page 72] – Key-Value Dictionary
- Erlang Module digraph [page 76] – Directed Graphs
- Erlang Module digraph_utils [page 83] – Algorithms for Directed Graphs
- Erlang Module epp [page 87] – An Erlang Code Preprocessor
- Erlang Module erl_eval [page 89] – The Erlang Meta Interpreter
- Erlang Module erl_id_trans [page 92] – An Identity Parse Transform
- Erlang Module erl_internal [page 93] – Internal Erlang Definitions
- Erlang Module erl_lint [page 95] – The Erlang Code Linter
- Erlang Module erl_parse [page 98] – The Erlang Parser
- Erlang Module erl_pp [page 101] – The Erlang Pretty Printer
- Erlang Module erl_scan [page 104] – The Erlang Token Scanner
- Erlang Module ets [page 106] – Built-In Term Storage
- Erlang Module file_sorter [page 122] – File Sorter
- Erlang Module filename [page 127] – File Name Manipulation Functions
- Erlang Module gb_sets [page 132] – General Balanced Trees
- Erlang Module gb_trees [page 136] – General Balanced Trees
- Erlang Module gen_event [page 139] – Generic Event Handling Behaviour
- Erlang Module gen_fsm [page 148] – Generic Finite State Machine Behaviour
- Erlang Module gen_server [page 157] – Generic Server Behaviour
- Erlang Module io [page 165] – Standard I/O Server Interface Functions
- Erlang Module io_lib [page 172] – IO Library Functions
- Erlang Module lib [page 175] – Interface Module
- Erlang Module lists [page 176] – List Processing Functions
- Erlang Module log_mfh [page 187] – An Event Handler which Logs Events to Disk
beam_lib

The following functions are exported:

- chunks(FileNameOrBinary, [ChunkRef]) -> {ok, {Module, [ChunkData]}} |
  {error, Module, Reason}  [page 45] Read selected chunks from a BEAM file or binary
- version(FileNameOrBinary) -> {ok, {Module, Version}} |
  {error, Module, Reason}  [page 45] Read the BEAM file's module version
- info(FileNameOrBinary) -> [SourceRef, {module, Module}, [chunks, [ChunkInfo]]] |
  {error, Module, Reason}  [page 45] Return some information about a BEAM file
- cmp(FileNameOrBinary, FileNameOrBinary) -> ok |
  {error, Module, Reason}  [page 45] Compare two BEAM files
• `cmp_dirs(Directory1, Directory2) -> {Only1, Only2, Different} | {error, Module, Reason}`
  [page 46] Compare the BEAM files in two directories
• `diff_dirs(Directory1, Directory2) -> ok | {error, Module, Reason}`
  [page 46] Compares the BEAM files in two directories
• `strip(FileNameOrBinary) -> {ok, Module, FileNameOrBinary} | {error, Module, Reason}`
  [page 46] Removes chunks not needed by the loader from a BEAM file
• `strip_files(Files) -> {ok, [{Module, FileNameOrBinary}]} | {error, Module, Reason}`
  [page 46] Removes chunks not needed by the loader from BEAM files
• `strip_release(Directory) -> {ok, [{Module, FileName}]} | {error, Module, Reason}`
  [page 47] Removes chunks not needed by the loader from all BEAM files of a release
• `format_error(Error) -> character_list()`
  [page 47] Return an English description of a BEAM read error reply

C

The following functions are exported:

• `bt(Pid) -> void()`
  [page 48] Evaluate `erlang:process_display(Pid, backtrace)`
• `c(File) -> CompileResult`
  [page 48] Compile a file
• `c(File, Flags) -> CompileResult`
  [page 48] Compile a file
• `cd(Dir) -> void()`
  [page 48] Change directory
• `flush() -> void()`
  [page 49] Flush the shell message queue
• `help() -> void()`
  [page 49] Display help information
• `i() -> void()`
  [page 49] Display system information
• `i(X, Y, Z) -> void()`
  [page 49] Evaluate `process_info(pid(X, Y, Z))`
• `l(Module) -> void()`
  [page 49] Load code into the system
• `lc(ListOfFiles) -> Result`
  [page 49] Compile several files
• `ls() -> void()`
  [page 49] List files
• `ls(Dir) -> void()`
  [page 49] List files in Dir
• `m() -> void()`
  [page 49] List all loaded modules
- `m(Module)` -> `void()`  
  [page 50] Display information about a module
- `memory()` -> `TupleList`  
  [page 50] Return memory allocation information
- `memory(MemoryType)` -> `int()`  
  [page 50] Return memory allocation information
- `nc(File)` -> `void()`  
  [page 51] Compile file and loads it on multiple nodes
- `nc(File, Flags)` -> `void()`  
  [page 51] Compile file and loads it on multiples nodes
- `ni()` -> `void()`  
  [page 51] Display network information
- `nl(Module)` -> `void()`  
  [page 51] Load module in a network
- `nregs()` -> `void()`  
  [page 51] Display registered processes on all nodes
- `pid(X, Y, Z)` -> `pid()`  
  [page 51] Make a Pid
- `pwd()` -> `void()`  
  [page 52] Print current working directory
- `q()` -> `void()`  
  [page 52] Stop the Erlang node
- `regs()` -> `void()`  
  [page 52] Display registered processes
- `xm(ModSpec)` -> `void()`  
  [page 52] Cross reference check a module
- `zi()` -> `void()`  
  [page 52] Display system information including zombies

### calendar

The following functions are exported:

- `date_to_gregorian_days(Year, Month, Day)` -> `Days`  
  [page 53] Compute the number of days from year 0 up to the given date.
- `date_to_gregorian_days(Date)` -> `Days`  
  [page 53] Compute the number of days from year 0 up to the given date.
- `datetime_to_gregorian_seconds(DateTime)` -> `Days`  
  [page 53] Compute the number of seconds from year 0 up to the given date and time.
- `day_of_the_week(Date)` -> `DayNumber`  
  [page 54] Compute the day of the week
- `day_of_the_week(Year, Month, Day)` -> `DayNumber`  
  [page 54] Compute the day of the week
- `gregorian_days_to_date(Days)` -> `Date`  
  [page 54] Compute the date given the number of gregorian days.
• `gregorian_seconds_to_datetime(Seconds) -> DateTime`
  [page 54] Compute the date given the number of gregorian days.
• `is_leap_year(Year) -> bool()`
  [page 54] Check if a year is a leap year.
• `last_day_of_the_month(Year, Month) -> int()`
  [page 54] Compute the number of days in a month
• `local_time() -> {Date, Time}`
  [page 55] Compute local time
• `local_time_to_universal_time({Date, Time}) -> {Date, Time}`
  [page 55] Convert from local time to universal time.
• `now_to_local_time(Now) -> {Date, Time}`
  [page 55] Convert now to local date and time
• `now_to_universal_time(Now) -> {Date, Time}`
  [page 55] Convert now to date and time
• `now_to_datetime(Now) -> {Date, Time}`
  [page 55] Convert now to date and time
• `seconds_to_daystime(Seconds) -> {Days, Time}`
  [page 55] Compute a days and time from seconds.
• `seconds_to_time(Seconds) -> Time`
  [page 56] Compute time from seconds
• `time_difference(T1, T2) -> Tdiff`
  [page 56] Compute the difference between two times
• `time_to_seconds(Time) -> Seconds`
  [page 56] Compute the number of seconds since midnight up to the given time.
• `universal_time() -> {Date, Time}`
  [page 56] Compute universal time
• `universal_time_to_local_time({Date, Time}) -> {Date, Time}`
  [page 56] Convert from universal time to local time.
• `valid_date(Date) -> bool()`
  [page 57] Check if a date is valid
• `valid_date(Year, Month, Day) -> bool()`
  [page 57] Check if a date is valid

dets

The following functions are exported:
• `all() -> [Name]`
  [page 59] Return a list of the names of all open Dets tables on this node.
• `bchunk(Name, Continuation) -> {Continuation2, Data} | '$end_of_table' | {error, Reason}`
  [page 59] Return a chunk of objects stored in a Dets table.
• `close(Name) -> ok | {error, Reason}`
  [page 60] Close a Dets table.
• `delete(Name, Key) -> ok | {error, Reason}`
  [page 60] Delete all objects with a given key from a Dets table.
- delete_all_objects(Name) -> ok | {error, Reason}  
  [page 60] Delete all objects from a Dets table.
- delete_object(Name, Object) -> ok | {error, Reason}  
  [page 60] Delete a given object from a Dets table.
- first(Name) -> Key | '$end_of_table'  
  [page 60] Return the first key stored in a Dets table.
- foldl(Function, Acc0, Name) -> Acc1 | {error, Reason}  
  [page 61] Fold a function over a Dets table.
- foldr(Function, Acc0, Name) -> Acc1 | {error, Reason}  
  [page 61] Fold a function over a Dets table.
- from_ets(Name, EtsTab) -> ok | {error, Reason}  
  [page 61] Replace the objects of a Dets table with the objects of an Ets table.
- info(Name) -> InfoList | undefined  
  [page 61] Return information about a Dets table.
- info(Name, Item) -> Value | undefined  
  [page 62] Return the information associated with a given item for a Dets table.
- init_table(Name, InitFun [, Options]) -> ok | {error, Reason}  
  [page 62] Replace all objects of a Dets table.
- insert(Name, Objects) -> ok | {error, Reason}  
  [page 63] Insert one or more objects into a Dets table.
- is_dets_file(FileName) -> Bool | {error, Reason}  
  [page 63] Test for a Dets table.
- lookup(Name, Key) -> [Object] | {error, Reason}  
  [page 64] Return all objects with a given key stored in a Dets table.
- match(Continuation) -> [{Match], Continuation2} | '$end_of_table' | {error, Reason}  
  [page 64] Match a chunk of objects stored in a Dets table and return a list of variable bindings.
- match(Name, Pattern) -> [Match] | {error, Reason}  
  [page 64] Match the objects stored in a Dets table and return a list of variable bindings.
- match(Name, Pattern, N) -> [{Match], Continuation} | '$end_of_table' | {error, Reason}  
  [page 64] Match the first chunk of objects stored in a Dets table and return a list of variable bindings.
- match_delete(Name, Pattern) -> N | {error, Reason}  
  [page 65] Delete all objects that match a given pattern from a Dets table.
- match_object(Continuation) -> [{Object], Continuation2} | '$end_of_table' | {error, Reason}  
  [page 65] Match a chunk of objects stored in a Dets table and return a list of objects.
- match_object(Name, Pattern) -> [Object] | {error, Reason}  
  [page 65] Match the objects stored in a Dets table and return a list of objects.
- match_object(Name, Pattern, N) -> [{Object], Continuation} | '$end_of_table' | {error, Reason}  
  [page 66] Match the first chunk of objects stored in a Dets table and return a list of objects.
- `member(Name, Key) -> Bool | {error, Reason}`
  [page 66] Test for occurrence of a key in a Dets table.
- `next(Name, Key1) -> Key2 | '$end_of_table'`
  [page 66] Return the next key in a Dets table.
- `open_file(Filename) -> {ok, Reference} | {error, Reason}`
  [page 67] Open an existing Dets table.
- `open_file(Name, Args) -> {ok, Name} | {error, Reason}`
  [page 67] Open a Dets table.
- `pid2name(Pid) -> {ok, Name} | undefined`
  [page 68] Return the name of the Dets table handled by a pid.
- `safe_fixtable(Name, Fix)`
  [page 68] Fix a Dets table for safe traversal.
- `select(Continuation) -> {Selection, Continuation2} | '$end_of_table' | {error, Reason}`
  [page 69] Apply a match specification to some objects stored in a Dets table.
- `select(Name, MatchSpec) -> Selection | {error, Reason}`
  [page 69] Apply a match specification to all objects stored in a Dets table.
- `select(Name, MatchSpec, N) -> {Selection, Continuation} | '$end_of_table' | {error, Reason}`
  [page 69] Apply a match specification to the first chunk of objects stored in a Dets table.
- `select_delete(Name, MatchSpec) -> N | {error, Reason}`
  [page 70] Delete all objects that match a given pattern from a Dets table.
- `slot(Name, I) -> '$end_of_table' | [Object] | {error, Reason}`
  [page 70] Return the list of objects associated with a slot of a Dets table.
- `sync(Name) -> ok | {error, Reason}`
  [page 70] Ensure that all updates made to a Dets table are written to disk.
- `to_ets(Name, EtsTab) -> EtsTab | {error, Reason}`
  [page 70] Insert all objects of a Dets table into an Ets table.
- `traverse(Name, Fun) -> Return | {error, Reason}`
  [page 70] Apply a function to all or some objects stored in a Dets table.
- `update_counter(Name, Key, Increment) -> Result`
  [page 71] Update a counter object stored in a Dets table.

dict

The following functions are exported:

- `append(Key, Value, Dict1) -> Dict2`
  [page 72] Append a value to keys in a dictionary
- `append_list(Key, ValList, Dict1) -> Dict2`
  [page 72] Append new values to keys in a dictionary
- `erase(Key, Dict1) -> Dict2`
  [page 72] Erase a key from a dictionary
- `fetch(Key, Dict) -> Value`
  [page 72] Look-up values in a dictionary
• fetch_keys(Dict) -> Keys
  [page 73] Return all keys in a dictionary

• filter(Pred, Dict1) -> Dict2
  [page 73] Choose elements which satisfy a predicate

• find(Key, Dict) -> Result
  [page 73] Search for a key in a dictionary

• fold(Function, Acc0, Dict) -> Acc1
  [page 73] Fold a function over a dictionary

• from_list(List) -> Dict
  [page 73] Convert a list of pairs to a dictionary

• is_key(Key, Dict) -> bool()
  [page 73] Test if a key is in a dictionary.

• map(Func, Dict1) -> Dict2
  [page 73] Map a function over a dictionary

• merge(Func, Dict1, Dict2) -> Dict3
  [page 74] Merge two dictionaries

• new() -> dictionary()
  [page 74] Create a dictionary

• store(Key, Value, Dict1) -> Dict2
  [page 74] Store a value in a dictionary

• to_list(Dict) -> List
  [page 74] Convert a dictionary to a list of pairs

• update(Key, Function, Dict) -> Dict
  [page 74] Update a value in a dictionary

• update(Key, Function, Initial, Dict) -> Dict
  [page 75] Update a value in a dictionary

• update_counter(Key, Increment, Dict) -> Dict
  [page 75] Increment a value in a dictionary

digraph

The following functions are exported:

• add_edge(G, E, V1, V2, Label) -> edge() | {error, Reason}
  [page 76] Add an edge to a digraph.

• add_edge(G, V1, V2, Label) -> edge() | {error, Reason}
  [page 76] Add an edge to a digraph.

• add_edge(G, V1, V2) -> edge() | {error, Reason}
  [page 76] Add an edge to a digraph.

• add_vertex(G, V, Label) -> vertex()
  [page 77] Add or modify a vertex of a digraph.

• add_vertex(G, V) -> vertex()
  [page 77] Add or modify a vertex of a digraph.

• add_vertex(G) -> vertex()
  [page 77] Add or modify a vertex of a digraph.

• del_edge(G, E) -> true
  [page 77] Delete an edge from a digraph.
- `del_edges(G, Edges) --> true`  
  [page 77] Delete edges from a digraph.
- `del_path(G, V1, V2) --> true`  
  [page 77] Delete paths from a digraph.
- `del_vertex(G, V) --> true`  
  [page 78] Delete a vertex from a digraph.
- `del_vertices(G, Vertices) --> true`  
  [page 78] Delete vertices from a digraph.
- `delete(G) --> true`  
  [page 78] Delete a digraph.
- `edge(G, E) --> {E, V1, V2, Label} | false`  
  [page 78] Return the vertices and the label of an edge of a digraph.
- `edges(G) --> Edges`  
  [page 78] Return all edges of a digraph.
- `edges(G, V) --> Edges`  
  [page 78] Return the edges emanating from or incident on a vertex of a digraph.
- `get_cycle(G, V) --> Vertices | false`  
  [page 79] Find one cycle in a digraph.
- `get_path(G, V1, V2) --> Vertices | false`  
  [page 79] Find one path in a digraph.
- `get_short_cycle(G, V) --> Vertices | false`  
  [page 79] Find one short cycle in a digraph.
- `get_short_path(G, V1, V2) --> Vertices | false`  
  [page 79] Find one short path in a digraph.
- `in_degree(G, V) --> integer()`  
  [page 80] Return the in-degree of a vertex of a digraph.
- `in_edges(G, V) --> Edges`  
  [page 80] Return all edges incident on a vertex of a digraph.
- `in_neighbours(G, V) --> Vertices`  
  [page 80] Return all in-neighbours of a vertex of a digraph.
- `info(G) --> InfoList`  
  [page 80] Return information about a digraph.
- `new() --> digraph()`  
  [page 81] Return a protected empty digraph, where cycles are allowed.
- `new(Type) --> digraph() | {error, Reason}`  
  [page 81] Create a new empty digraph.
- `no_edges(G) --> integer() >= 0`  
  [page 81] Return the number of edges of the a digraph.
- `no_vertices(G) --> integer() >= 0`  
  [page 81] Return the number of vertices of a digraph.
- `out_degree(G, V) --> integer()`  
  [page 81] Return the out-degree of a vertex of a digraph.
- `out_edges(G, V) --> Edges`  
  [page 81] Return all edges emanating from a vertex of a digraph.
- `out_neighbours(G, V) --> Vertices`  
  [page 81] Return all out-neighbours of a vertex of a digraph.
digraph utils

The following functions are exported:

- `components(Digraph) -> [Component]`  
  [page 84] Return the components of a digraph.
- `condensation(Digraph) -> CondensedDigraph`  
  [page 84] Return a condensed graph of a digraph.
- `cyclic_strong_components(Digraph) -> [StrongComponent]`  
  [page 84] Return the cyclic strong components of a digraph.
- `is_acyclic(Digraph) -> bool()`  
  [page 84] Check if a digraph is acyclic.
- `loop_vertices(Digraph) -> Vertices`  
  [page 84] Return the vertices of a digraph included in some loop.
- `postorder(Digraph) -> Vertices`  
  [page 85] Return the vertices of a digraph in post-order.
- `preorder(Digraph) -> Vertices`  
  [page 85] Return the vertices of a digraph in pre-order.
- `reachable(Vertices, Digraph) -> Vertices`  
  [page 85] Return the vertices reachable from some vertices of a digraph.
- `reachable_neighbours(Vertices, Digraph) -> Vertices`  
  [page 85] Return the neighbours reachable from some vertices of a digraph.
- `reaching(Vertices, Digraph) -> Vertices`  
  [page 85] Return the vertices that reach some vertices of a digraph.
- `reaching_neighbours(Vertices, Digraph) -> Vertices`  
  [page 85] Return the neighbours that reach some vertices of a digraph.
- `strong_components(Digraph) -> [StrongComponent]`  
  [page 86] Return the strong components of a digraph.
- `subgraph(Digraph, Vertices [, Options]) -> Subgraph | {error, Reason}`  
  [page 86] Return a subgraph of a digraph.
- `topsort(Digraph) -> Vertices | false`  
  [page 86] Return a topological sorting of the vertices of a digraph.

epp

The following functions are exported:

- `open(FileName, IncludePath) -> {ok, Epp} | {error, ErrorDescriptor}`  
  [page 87] Open a file for preprocessing.
- `open(FileName, IncludePath, PredefMacros) -> {ok, Epp} | {error, ErrorDescriptor}`  
  [page 87] Open a file for preprocessing.
• close(Epp) -> ok
  [page 87] Close the preprocessing of the file associated with Epp
• parse_erl_form(Epp) -> {ok, AbsForm} | {eof, Line} | {error, ErrorInfo}
  [page 87] Return the next Erlang form from the opened Erlang source file
• parse_file(FileName,IncludePath,PredefMacro) -> {ok,[Form]} | {error,OpenError}
  [page 87] Preprocess and parse an Erlang source file

erl_eval

The following functions are exported:

• exprs(Expressions, Bindings) -> {value, Value, NewBindings}
  [page 89] Evaluate expressions
• exprs(Expressions, Bindings, LocalFunctionHandler) -> {value, Value, NewBindings}
  [page 89] Evaluate expressions
• expr(Expression, Bindings) -> {value, Value, NewBindings}
  [page 89] Evaluate expression
• expr(Expression, Bindings, LocalFunctionHandler) -> {value, Value, NewBindings}
  [page 89] Evaluate expression
• expr_list(ExpressionList, Bindings) -> {ValueList, NewBindings}
  [page 89] Evaluate a list of expressions
• expr_list(ExpressionList, Bindings, LocalFunctionHandler) -> {ValueList, NewBindings}
  [page 89] Evaluate a list of expressions
• new_bindings() -> BindingStruct
  [page 90] Return a bindings structure
• bindings(BindingStruct) -> Bindings
  [page 90] Return bindings
• binding(Name, BindingStruct) -> Binding
  [page 90] Return bindings
• add_binding(Name, Value, Bindings) -> BindingStruct
  [page 90] Add a binding
• del_binding(Name, Bindings) -> BindingStruct
  [page 90] Delete a binding

erl_id_trans

The following functions are exported:

• parse_transform(Forms, Options) -> Forms
  [page 92] Transform Erlang forms
erl_internal

The following functions are exported:

- `bif(Name, Arity) -> bool()`  
  [page 93] Test for an Erlang BIF

- `guard_bif(Name, Arity) -> bool()`  
  [page 93] Test for an Erlang BIF allowed in guards

- `type_test(Name, Arity) -> bool()`  
  [page 93] Test for a valid type test

- `arith_op(OpName, Arity) -> bool()`  
  [page 93] Test for an arithmetic operator

- `bool_op(OpName, Arity) -> bool()`  
  [page 93] Test for a Boolean operator

- `comp_op(OpName, Arity) -> bool()`  
  [page 94] Test for a comparison operator

- `list_op(OpName, Arity) -> bool()`  
  [page 94] Test for a list operator

- `send_op(OpName, Arity) -> bool()`  
  [page 94] Test for a send operator

- `op_type(OpName, Arity) -> Type`  
  [page 94] Return operator type

erl_lint

The following functions are exported:

- `module(AbsForms) -> {ok,Warnings} | {error,Errors,Warnings}`  
  [page 95] Check a module for errors

- `module(AbsForms, FileName) -> {ok,Warnings} | {error,Errors,Warnings}`  
  [page 95] Check a module for errors

- `module(AbsForms, FileName, CompileOptions) -> {ok,Warnings} | {error,Errors,Warnings}`  
  [page 95] Check a module for errors

- `is_guard_test(Expr) -> bool()`  
  [page 96] Test for a guard test

- `format_error(ErrorCode) -> string()`  
  [page 96] Format an error descriptor

erl_parse

The following functions are exported:

- `parse_form(Tokens) -> {ok,AbsForm} | {error,ErrorInfo}`  
  [page 98] Parse an Erlang form

- `parse_exprs(Tokens) -> {ok,ExprList} | {error,ErrorInfo}`  
  [page 98] Parse Erlang expressions
STDLIB Reference Manual

- `parse_term(Tokens) -> {ok, Term} | {error, ErrorInfo}
  [page 98] Parse an Erlang term
- `format_error(ErrorDescriptor) -> string()
  [page 99] Format an error descriptor
- `tokens(AbsTerm) -> Tokens
  [page 99] Generate a list of tokens for an expression
- `tokens(AbsTerm, MoreTokens) -> Tokens
  [page 99] Generate a list of tokens for an expression
- `normalise(AbsTerm) -> Data
  [page 99] Convert abstract form to an Erlang term
- `abstract(Data) -> AbsTerm
  [page 99] Convert a Erlang term into an abstract form

erl_pp

The following functions are exported:

- `form(Form) -> DeepCharList
  [page 101] Pretty print a form
- `form(Form, HookFunction) -> DeepCharList
  [page 101] Pretty print a form
- `attribute(Attribute) -> DeepCharList
  [page 101] Pretty print an attribute
- `attribute(Attribute, HookFunction) -> DeepCharList
  [page 101] Pretty print an attribute
- `function(Function) -> DeepCharList
  [page 101] Pretty print a function
- `function(Function, HookFunction) -> DeepCharList
  [page 101] Pretty print a function
- `guard(Guard) -> DeepCharList
  [page 101] Pretty print a guard
- `guard(Guard, HookFunction) -> DeepCharList
  [page 101] Pretty print a guard
- `exprs(Expressions) -> DeepCharList
  [page 102] Pretty print Expressions
- `exprs(Expressions, HookFunction) -> DeepCharList
  [page 102] Pretty print Expressions
- `exprs(Expressions, Indent, HookFunction) -> DeepCharList
  [page 102] Pretty print Expressions
- `expr(Expression) -> DeepCharList
  [page 102] Pretty print one Expression
- `expr(Expression, HookFunction) -> DeepCharList
  [page 102] Pretty print one Expression
- `expr(Expression, Indent, HookFunction) -> DeepCharList
  [page 102] Pretty print one Expression
- `expr(Expression, Indent, Precedence, HookFunction) -> DeepCharList
  [page 102] Pretty print one Expression
erl\_scan

The following functions are exported:

- \texttt{string(CharList,StartLine}) \rightarrow \{ok, Tokens, EndLine\} | Error
  \hspace{1em} [page 104] Scan a string and returns the Erlang tokens
- \texttt{string(CharList)} \rightarrow \{ok, Tokens, EndLine\} | Error
  \hspace{1em} [page 104] Scan a string and returns the Erlang tokens
- \texttt{tokens(Continuation, CharList, StartLine)} \rightarrow \texttt{Return}
  \hspace{1em} [page 104] Re-entrant scanner
- \texttt{reserved\_word(Atom)} \rightarrow \texttt{bool()}
  \hspace{1em} [page 105] Test for a reserved word
- \texttt{format\_error(ErrorDescriptor)} \rightarrow \texttt{string()}
  \hspace{1em} [page 105] Format an error descriptor

\texttt{ets}

The following functions are exported:

- \texttt{all()} \rightarrow \[Tab\]
  \hspace{1em} [page 107] Return a list of all ETS tables
- \texttt{delete(Tab)} \rightarrow \texttt{true}
  \hspace{1em} [page 107] Delete an entire ETS table.
- \texttt{delete(Tab, Key)} \rightarrow \texttt{true}
  \hspace{1em} [page 107] Delete all objects with a given key from an ETS table.
- \texttt{delete\_all\_objects(Tab)} \rightarrow \texttt{true}
  \hspace{1em} [page 107] Delete all objects in an ETS table.
- \texttt{delete\_object(Tab, Object)} \rightarrow \texttt{true}
  \hspace{1em} [page 107] Deletes a specific from an ETS table.
- \texttt{file2tab(Filename)} \rightarrow \{ok,Tab\} | \{error,Reason\}
  \hspace{1em} [page 107] Read an ETS table from a file.
- \texttt{first(Tab)} \rightarrow \texttt{Key | 'end\_of\_table'}
  \hspace{1em} [page 107] Return the first key in an ETS table.
- \texttt{fixtable(Tab, true|false)} \rightarrow \texttt{true | false}
  \hspace{1em} [page 108] Fix an ETS table for safe traversal (obsolete).
- \texttt{foldl(Function, Acc0, Tab)} \rightarrow \texttt{Acc1}
  \hspace{1em} [page 108] Fold a function over an ETS table
- \texttt{foldr(Function, Acc0, Tab)} \rightarrow \texttt{Acc1}
  \hspace{1em} [page 108] Fold a function over an ETS table
- \texttt{from\_dets(Tab, DetsTab)} \rightarrow \texttt{Tab}
  \hspace{1em} [page 108] Fill an ETS table with the objects from a DETS table.
- \texttt{fun2ms(LiteralFun)} \rightarrow \texttt{MatchSpec}
  \hspace{1em} [page 109] Pseudo function that transforms fun syntax to match\_spec.
- \texttt{i()} \rightarrow \texttt{void()}
  \hspace{1em} [page 110] Display information about all ETS tables on tty.
- \texttt{i(Tab)} \rightarrow \texttt{void()}
  \hspace{1em} [page 110] Browse an ETS table on tty.
- `info(Tab) -> [{Item,Value}] | undefined`
  [page 110] Return information about an ETS table.
- `info(Tab, Item) -> Value | undefined`
  [page 111] Return the information associated with given item for an ETS table.
- `init_table(Name, InitFun) -> true`
  [page 111] Replace all objects of an ETS table.
- `insert(Tab, ObjectOrObjects) -> true`
  [page 111] Insert an object into an ETS table.
- `last(Tab) -> Key | '$end_of_table'`
  [page 112] Return the last key in an ETS table of type ordered_set.
- `lookup(Tab, Key) -> [Object]`
  [page 112] Return all objects with a given key in an ETS table.
- `lookup_element(Tab, Key, Pos) -> Elem`
  [page 112] Return the Pos:th element of all objects with a given key in an ETS table.
- `match(Tab, Pattern) -> [Match]`
  [page 112] Match the objects in an ETS table against a pattern.
- `match(Tab, Pattern, Limit) -> [{Match},Continuation] | '$end_of_table'`
  [page 113] Match the objects in an ETS table against a pattern and returns part of the answers.
- `match(Continuation) -> [{Match},Continuation] | '$end_of_table'`
  [page 113] Continues matching objects in an ETS table.
- `match_delete(Tab, Pattern) -> true`
  [page 114] Delete all objects which match a given pattern from an ETS table.
- `match_object(Tab, Pattern) -> [Object]`
  [page 114] Match the objects in an ETS table against a pattern.
- `match_object(Tab, Pattern, Limit) -> [{Match},Continuation] | '$end_of_table'`
  [page 114] Match the objects in an ETS table against a pattern and returns part of the answers.
- `match_object(Continuation) -> [{Match},Continuation] | '$end_of_table'`
  [page 114] Continues matching objects in an ETS table.
- `member(Tab, Key) -> true | false`
- `new(Name, Options) -> tid()`
  [page 115] Create a new ETS table.
- `next(Tab, Key1) -> Key2 | '$end_of_table'`
  [page 115] Return the next key in an ETS table.
- `prev(Tab, Key1) -> Key2 | '$end_of_table'`
  [page 116] Return the previous key in an ETS table of type ordered_set.
- `rename(Tab, Name) -> Name`
  [page 116] Rename a named ETS table.
- `safe_fixtable(Tab, true|false) -> true | false`
  [page 116] Fix an ETS table for safe traversal.
• `select(Tab, MatchSpec) -> [Object]`
  [page 117] Match the objects in an ETS table against a match_spec.

• `select(Tab, MatchSpec, Limit) -> {{Match}, Continuation} | "$end_of_table"
  [page 118] Match the objects in an ETS table against a match_spec and returns
  part of the answers.

• `select(Continuation) -> {{Match}, Continuation} | "$end_of_table"

• `select_delete(Tab, MatchSpec) -> NumDeleted`
  [page 119] Match the objects in an ETS table against a match_spec and deletes
  objects where the match_spec returns 'true'.

• `select_count(Tab, MatchSpec) -> NumMatched`
  [page 119] Match the objects in an ETS table against a match_spec and returns the
  number of objects for which the match_spec returned 'true'.

• `slot(Tab, I) -> [Object] | "$end_of_table"
  [page 120] Return all objects in a given slot of an ETS table.

• `tab2file(Tab, Filename) -> ok | {error, Reason}
  [page 120] Dump an ETS table to a file.

• `tab2list(Tab) -> [Object]
  [page 120] Return a list of all objects in an ETS table.

• `test_ms(Tuple, MatchSpec) -> {ok, Result} | {error, Errors}
  [page 120] Test a match_spec for use in ets:select/2.

• `to_dets(Tab, DetsTab) -> Tab
  [page 121] Fill a DETS table with the objects from an ETS table.

• `update_counter(Tab, Key, {Pos, Incr}) -> Result`
  [page 121] Update a counter object in an ETS table.

• `update_counter(Tab, Key, Incr) -> Result`
  [page 121] Update a counter object in an ETS table.

**file_sorter**

The following functions are exported:

• `sort(FileName) -> Reply`
  [page 125] Sort terms on files.

• `sort(Input, Output) -> Reply`
  [page 125] Sort terms on files.

• `sort(Input, Output, Options) -> Reply`
  [page 125] Sort terms on files.

• `keysort(KeyPos, FileName) -> Reply`
  [page 125] Sort terms on files by key.

• `keysort(KeyPos, Input, Output) -> Reply`
  [page 125] Sort terms on files by key.

• `keysort(KeyPos, Input, Output, Options) -> Reply`
  [page 125] Sort terms on files by key.

• `merge(FileNames, Output) -> Reply`
  [page 125] Merge terms on files.
The following functions are exported:

- `merge(Filenames, Output, Options) -> Reply`
  - Merge terms on files.

- `keymerge(KeyPos, Filenames, Output) -> Reply`
  - Merge terms on files by key.

- `keymerge(KeyPos, Filenames, Output, Options) -> Reply`
  - Merge terms on files by key.

- `check(Filename) -> Reply`
  - Check whether terms on files are sorted.

- `check(Filenames, Options) -> Reply`
  - Check whether terms on files are sorted.

- `keycheck(KeyPos, Filename) -> CheckReply`
  - Check whether terms on files are sorted by key.

- `keycheck(KeyPos, Filenames, Options) -> Reply`
  - Check whether terms on files are sorted by key.

`filename`

The following functions are exported:

- `absname(Filename) -> Absname`
  - Convert a relative Filename to an absolute name.

- `absname(Filename, Directory) -> Absname`
  - Convert the relative Filename to an absolute name, based on Directory.

- `basename(Filename)`
  - Return the part of the Filename after the last directory separator.

- `basename(Filename, Ext) -> string()`
  - Return the last component of Filename with Ext stripped.

- `dirname(Filename) -> string()`
  - Return the directory part of a path name.

- `extension(Filename) -> string() | []`
  - Return the file extension.

- `join(Components) -> string()`
  - Join a list of file name Components with directory separators.

- `join(Name1, Name2) -> string()`
  - Join two file name components with directory separators.

- `nativename(Path) -> string()`
  - Return the native form of a file Path.

- `pathtype(Path) -> absolute | relative | volumerelative`
  - Return the type of a Path.

- `rootname(Filename) -> string()`
  - Return all characters in Filename, except the extension.

- `rootname(Filename, Ext) -> string()`
  - Return all characters in Filename, except the extension.

- `split(Filename) -> Components`
  - Return a list whose elements are the file name components of Filename.
• \texttt{find_src(Module)} \rightarrow \{\texttt{SourceFile}, \texttt{Options}\}
  
  [page 130] Find the Filename and compilation options for a compiled Module.

• \texttt{find_src(Module, Rules)} \rightarrow \{\texttt{SourceFile}, \texttt{Options}\}
  
  [page 130] Find the Filename and compilation options for a compiled Module.

\textbf{gb_sets}

The following functions are exported:

• \texttt{empty()}
  
  [page 132] get empty set

• \texttt{is_empty(S)}
  
  [page 132] check if empty

• \texttt{size(S)}
  
  [page 132] get number of elements

• \texttt{singleton(X)}
  
  [page 132] new set with one element

• \texttt{is_member(X, S)}
  
  [page 132] check for member

• \texttt{insert(X, S)}
  
  [page 133] insert new element

• \texttt{add(X, S)}
  
  [page 133] add element

• \texttt{delete(X, S)}
  
  [page 133] delete element

• \texttt{delete_any(X, T)}
  
  [page 133] removes key if present

• \texttt{balance(S)}
  
  [page 133] rebalance tree representation

• \texttt{union(S1, S2)}
  
  [page 133] union of set

• \texttt{union(Ss)}
  
  [page 133] union of list of sets

• \texttt{intersection(S1, S2)}
  
  [page 133] intersection of sets

• \texttt{intersection(Ss)}
  
  [page 133] intersection of list of sets

• \texttt{difference(S1, S2)}
  
  [page 133] difference of sets

• \texttt{is_subset(S1, S2)}
  
  [page 134] check for subset

• \texttt{to_list(S)}
  
  [page 134] get list from set

• \texttt{from_list(List)}
  
  [page 134] make set from list

• \texttt{from_ordset(L)}
  
  [page 134] make set from ordset
- `take_smallest(S)`  
  [page 134] extract smallest element
- `iterator(S)`  
  [page 134] make iterator on set
- `next(T)`  
  [page 134] traverse with iterator
- `filter(P, S)`  
  [page 134] filter with predicate
- `fold(F, A, S)`  
  [page 134] fold with fun
- `is_set(S)`  
  [page 134] not recommended

**gb_trees**

The following functions are exported:

- `empty()`  
  [page 136] returns empty tree
- `is_empty(T)`  
  [page 136] true if tree is empty
- `size(T)`  
  [page 136] number of nodes in tree
- `lookup(X, T)`  
  [page 136] looks up key in tree
- `get(X, T)`  
  [page 136] retrieves value stored with key
- `insert(X, V, T)`  
  [page 137] inserts key and value in tree
- `update(X, V, T)`  
  [page 137] updates key to new value
- `enter(X, V, T)`  
  [page 137] inserts or updates key with value
- `delete(X, T)`  
  [page 137] removes key
- `delete_any(X, T)`  
  [page 137] removes key if present
- `balance(T)`  
  [page 137] rebalance tree
- `is_defined(X, T)`  
  [page 137] check if key exist
- `keys(T)`  
  [page 137] keys as list
- `values(T)`  
  [page 137] values as list
- `to_list(T)`  
  [page 137] keys and values as tuple-list
• from_orddict(L)  
  [page 137] make tree from orddict
• take_smallest(T)  
  [page 138] extract smallest key
• iterator(T)  
  [page 138] get iterator on tree
• next(S)  
  [page 138] iterate using iterator

**gen_event**

The following functions are exported:

• start() -> Result  
  [page 140] Create a generic event manager.
• start(EventMgrName) -> Result  
  [page 140] Create a generic event manager.
• start_link() -> Result  
  [page 140] Create a generic event manager.
• start_link(EventMgrName) -> Result  
  [page 140] Create a generic event manager.
• add_handler(EventMgrRef, Handler, Args) -> Result  
  [page 140] Add an event handler to a generic event manager.
• add_sup_handler(EventMgrRef, Handler, Args) -> Result  
  [page 141] Add a supervised event handler to a generic event manager.
• notify(EventMgrRef, Event) -> ok  
  [page 141] Notify an event manager about an event.
• sync_notify(EventMgrRef, Event) -> ok  
  [page 141] Notify an event manager about an event.
• call(EventMgrRef, Handler, Request) -> Result  
  [page 142] Make a synchronous call to a generic event manager.
• call(EventMgrRef, Handler, Request, Timeout) -> Result  
  [page 142] Make a synchronous call to a generic event manager.
• delete_handler(EventMgrRef, Handler, Args) -> Result  
  [page 142] Delete an event handler from a generic event manager.
• swap_handler(EventMgrRef, {Handler1,Args1}, {Handler2,Args2}) -> Result  
  [page 143] Replace an event handler in a generic event manager.
• swap_sup_handler(EventMgrRef, {Handler1,Args1}, {Handler2,Args2}) -> Result  
  [page 144] Replace an event handler in a generic event manager.
• which_handlers(EventMgrRef) -> [Handler]  
  [page 144] Return all event handlers installed in a generic event manager.
• stop(EventMgrRef) -> ok  
  [page 144] Terminate a generic event manager.
• Module:init(InitArgs) -> {ok,State}  
  [page 145] Initialize an event handler.
- **Module:** handle
  - `event(Event, State)` -> Result
    [page 145] Handle an event.
  - `call(Request, State)` -> Result
    [page 146] Handle a synchronous request.
  - `info(Info, State)` -> Result
    [page 146] Handle an incoming message.
  - `terminate(Arg, State)` -> `term()`
    [page 146] Clean up before deletion.
  - `code_change(OldVsn, State, Extra)` -> `{ok, NewState}`
    [page 147] Update the internal state due to code replacement

### gen_fsm

The following functions are exported:

- `start(Module, Args, Options)` -> Result
  [page 149] Create a generic FSM process.
- `start(FsmName, Module, Args, Options)` -> Result
  [page 149] Create a generic FSM process.
- `start_link(Module, Args, Options)` -> Result
  [page 149] Create a generic FSM process.
- `start_link(FsmName, Module, Args, Options)` -> Result
  [page 149] Create a generic FSM process.
- `send_event(FsmRef, Event)` -> `ok`
  [page 150] Send an event asynchronously to a generic FSM.
- `send_all_state_event(FsmRef, Event)` -> `ok`
  [page 150] Send an event asynchronously to a generic FSM.
- `sync_send_event(FsmRef, Event)` -> `Reply`
  [page 150] Send an event synchronously to a generic FSM.
- `sync_send_event(FsmRef, Event, Timeout)` -> `Reply`
  [page 150] Send an event synchronously to a generic FSM.
- `sync_send_all_state_event(FsmRef, Event)` -> `Reply`
  [page 151] Send an event synchronously to a generic FSM.
- `sync_send_all_state_event(FsmRef, Event, Timeout)` -> `Reply`
  [page 151] Send an event synchronously to a generic FSM.
- `reply(Caller, Reply)` -> `true`
  [page 151] Send a reply to a caller.
- `init(Arg)` -> Result
  [page 152] Initialize process and internal state name and state data.
- `StateName(Event, StateData)` -> Result
  [page 152] Handle an asynchronous event.
- `handle_event(Event, State)` -> Result
  [page 153] Handle an asynchronous event.
- `handle_event(Event, StateName, StateData)` -> Result
  [page 153] Handle a synchronous event.
- `Module:handle_sync_event(Event, From, StateName, StateData) -> Result`
  Handle a synchronous event.
- `Module:handle_info(Info, StateName, StateData) -> Result`
  Handle an incoming message.
- `Module:terminate(Reason, StateName, StateData)`
  Clean up before termination.
- `Module:code_change(OldVsn, StateName, StateData, Extra) -> {ok, NextStateName, NewStateData}`
  Update the state data due to code replacement.

**gen_server**

The following functions are exported:

- `start(Module, Args, Options) -> Result`
  Create a generic server process.
- `start(ServerName, Module, Args, Options) -> Result`
  Create a generic server process.
- `start_link(Module, Args, Options) -> Result`
  Create a generic server process.
- `start_link(ServerName, Module, Args, Options) -> Result`
  Create a generic server process.
- `call(ServerRef, Request) -> Reply`
  Make a synchronous call to a generic server.
- `call(ServerRef, Request, Timeout) -> Reply`
  Make a synchronous call to a generic server.
- `multi_call(Name, Request) -> Result`
  Make a synchronous call to several generic servers.
- `multi_call(Nodes, Name, Request) -> Result`
  Make a synchronous call to several generic servers.
- `multi_call(Nodes, Name, Request, Timeout) -> Result`
  Make a synchronous call to several generic servers.
- `cast(ServerRef, Request) -> ok`
  Send an asynchronous request to a generic server.
- `abcast(Name, Request) -> ok`
  Send an asynchronous request to several generic servers.
- `abcast(Nodes, Name, Request) -> ok`
  Send an asynchronous request to several generic servers.
- `reply(Client, Reply) -> true`
  Send a reply to a client.
- `Module:init(Args) -> Result`
  Initialize process and internal state.
- `Module:handle_call(Request, From, State) -> Result`
  Handle a synchronous request.
- `Module:handle_cast(Request, State) -> Result`
  Handle an asynchronous request.
- Module: handle_info(Info, State) \rightarrow Result
  [page 162] Handle an incoming message.
- Module: terminate(Reason, State)
  [page 163] Clean up before termination.
- Module: code_change(OldVsn, State, Extra) \rightarrow \{ok, NewState\}
  [page 163] Update the internal state due to code replacement.

io

The following functions are exported:

- put_chars([IoDevice,] Chars)
  [page 165] Write characters to standard output
- nl([IoDevice])
  [page 165] Output a newline
- get_chars([IoDevice,] Prompt, Count)
  [page 165] Read characters from standard input
- get_line([IoDevice,] Prompt)
  [page 165] Read a line from standard input
- write([IoDevice,] Term)
  [page 165] Write a term
- read([IoDevice,] Prompt)
  [page 165] Read a term
- fwrite(Format)
  [page 166] Write formatted output
- format(Format)
  [page 166] Write formatted output
- fwrite([IoDevice,] Format, Arguments)
  [page 166] Write formatted output
- format([IoDevice,] Format, Arguments)
  [page 166] Write formatted output
- fread([IoDevice,] Prompt, Format)
  [page 169] Read formatted input
- scan_erl_exprs(Prompt)
  [page 170] Read Erlang tokens
- scan_erl_exprs([IoDevice,] Prompt, StartLine)
  [page 170] Read Erlang tokens
- scan_erl_form(Prompt)
  [page 170] Read Erlang tokens
- scan_erl_form(IoDevice, Prompt[, StartLine])
  [page 170] Read Erlang tokens
- parse_erl_exprs(Prompt)
  [page 170] Read Erlang expressions
- parse_erl_exprs(IoDevice, Prompt[, StartLine])
  [page 170] Read Erlang expressions
- parse_erl_form(Prompt)
  [page 171] Read Erlang form
- parse_erl_form(IoDevice, Prompt[, StartLine])
  [page 171] Read Erlang form
io_lib

The following functions are exported:

- `nl()`  
  [page 172] Return a newline
- `write(Term)`  
  [page 172] Write a term
- `write(Term, Depth)`  
  [page 172] Write a term
- `print(Term)`  
  [page 172] Pretty print a term
- `print(Term, Column, LineLength, Depth)`  
  [page 172] Pretty print a term
- `fwrite(Format, Data)`  
  [page 172] List formatted output
- `format(Format, Data)`  
  [page 172] List formatted output
- `fread(Format, String)`  
  [page 172] List formatted input
- `fread(Continuation, CharList, Format)`  
  [page 173] Re-entrant formatted reader
- `write_atom(Atom)`  
  [page 173] Return an atom
- `write_string(String)`  
  [page 173] Return a string
- `write_char(Integer)`  
  [page 173] Return a character
- `indentation(String, StartIndent)`  
  [page 173] Indentation after printing string
- `char_list(CharList) -> bool()`  
  [page 173] Test for a list of characters
- `deep_char_list(CharList)`  
  [page 174] Test for a deep list of characters
- `printable_list(CharList)`  
  [page 174] Test for a list of printable characters

lib

The following functions are exported:

- `flush_receive() -> void()`  
  [page 175] Flush messages
- `error_message(Format, Args)`  
  [page 175] Print error message
- `progname() -> atom()`  
  [page 175] Return Erlang starter
lists

The following functions are exported:

- `nonl(List1)`  
  [page 175] Remove last newline
- `send(To, Msg)`  
  [page 175] Send a message
- `sendw(To, Msg)`  
  [page 175] Send a message and waits for an answer

- `append(ListOfLists)`  
  [page 176] Append a list of lists
- `append(List1, List2)`  
  [page 176] Append two lists
- `concat(Things)`  
  [page 177] Concatenate a list of atoms
- `delete(Element, List1)`  
  [page 177] Delete an element in a list
- `duplicate(N, Element)`  
  [page 177] Make N copies of element
- `flatlength(DeepList)`  
  [page 177] Length of flattened deep list
- `flatten(DeepList)`  
  [page 177] Flatten a deep list
- `flatten(DeepList, Tail)`  
  [page 177] Flatten a deep list
- `keydelete(Key, N, TupleList1)`  
  [page 178] Delete a tuple for a tuple list
- `keymember(Key, N, TupleList)`  
  [page 178] Test for a key in a list of tuples
- `keymerge(N, List1, List2)`  
  [page 178] Merge two key-sorted lists
- `keyreplace(Key, N, TupleList1, NewTuple)`  
  [page 178] Replace tuple in tuple list
- `keysearch(Key, N, TupleList)`  
  [page 178] Extract value of key in a list of tuples
- `keysort(N, List1)`  
  [page 178] Sort a list by key
- `last(List)`  
  [page 179] Return last element in a list
- `max(List)`  
  [page 179] Return maximum element of list
- `member(Element, List)`  
  [page 179] Test for membership of a list
- `merge(ListOfLists)`  
  [page 179] Merge a list of sorted lists
- `merge(List1, List2) -> List3`  
  [page 179] Merge two sorted lists

- `merge(Fun, List1, List2) -> List`  
  [page 179] Merge two sorted lists

- `merge3(List1, List2, List3) -> List4`  
  [page 180] Merge three sorted lists

- `min(List) -> Min`  
  [page 180] Return minimum element of list

- `nth(N, List) -> Element`  
  [page 180] Extract element from a list

- `nthtail(N, List1) -> List2`  
  [page 180] Return the N’th tail in List1

- `prefix(List1, List2) -> bool()`  
  [page 180] Test for list prefix

- `reverse(List1) -> List2`  
  [page 180] Reverse a list

- `reverse(List1, List2) -> List3`  
  [page 181] Reverse a list appending a tail

- `seq(From, To) -> [int()]`  
  [page 181] Generate a sequence of integers

- `seq(From, To, Incr) -> [int()]`  
  [page 181] Generate a sequence of integers

- `sort(List1) -> List2`  
  [page 181] Sort a list

- `sort(Fun, List1) -> List2`  
  [page 181] Sort a list

- `sublist(List, N) -> List1`  
  [page 181] Return the first N elements of List

- `sublist(List1, Start, Length) -> List2`  
  [page 182] Return a sub-list of list

- `subtract(List1, List2) -> List3`  
  [page 182] Subtract the element in one list from another list

- `suffix(List1, List2) -> bool()`  
  [page 182] Test for list suffix

- `sum(List) -> number()`  
  [page 182] Return sum of elements in a list

- `ukeymerge(N, List1, List2)`  
  [page 182] Merge two key-sorted lists and remove consecutive duplicates

- `ukeysort(N, List1) -> List2`  
  [page 182] Sort a list by key and remove consecutive duplicates

- `umerge(ListOfLists) -> List1`  
  [page 183] Merge a list of sorted lists without duplicates

- `umerge(List1, List2) -> List3`  
  [page 183] Merge two sorted lists without duplicates

- `umerge(Fun, List1, List2) -> List`  
  [page 183] Sort a list
- `umerge3(List1, List2, List3) -> List4`
  [page 183] Merge three sorted lists without duplicates
- `usort(List1) -> List2`
  [page 183] Sort a list and remove duplicates
- `usort(Fun, List1) -> List2`
  [page 183] Sort a list and remove duplicates
- `all(Pred, List) -> bool()`
  [page 184] Return true if all elements in the list satisfy `Pred`
- `any(Pred, List) -> bool()`
  [page 184] Return true if any of the elements X in the list satisfies `Pred(X)`
- `dropwhile(Pred, List1) -> List2`
  [page 184] Drop elements from `List1` while `Pred` is true
- `filter(Pred, List1) -> List2`
  [page 184] Choose elements which satisfy a predicate
- `flatmap(Function, List1) -> Element`
  [page 184] Map and flatten in one pass
- `foldl(Function, Acc0, List) -> Acc1`
  [page 184] Fold a function over a list
- `foldr(Function, Acc0, List) -> Acc1`
  [page 185] Fold a function over a list
- `foreach(Function, List) -> void()`  
  [page 185] Apply function to each element of a list
- `map(Func, List1) -> List2`
  [page 185] Map a function over a list
- `mapfoldl(Function, Acc0, List1) -> {List2, Acc}`
  [page 185] Map and fold in one pass
- `mapfoldr(Function, Acc0, List1) -> {List2, Acc}`
  [page 186] Map and fold in one pass
- `splitwith(Pred, List) -> {List1, List2}`
  [page 186] Partition `List1` into two lists according to `Pred`
- `takewhile(Pred, List1) -> List2`
  [page 186] Take elements from `List1` while `Pred` is true

**log\_mf\_h**

The following functions are exported:

- `init(Dir, MaxBytes, MaxFiles)`
  [page 187] Initiate the event handler
- `init(Dir, MaxBytes, MaxFiles, Pred) -> Args`
  [page 187] Initiate the event handler
math

The following functions are exported:

- `pi()` -> `float()`  [page 188] A useful number
- `sin(X)`  [page 188] Diverse math functions
- `cos(X)`  [page 188] Diverse math functions
- `tan(X)`  [page 188] Diverse math functions
- `asin(X)`  [page 188] Diverse math functions
- `acos(X)`  [page 188] Diverse math functions
- `atan(X)`  [page 188] Diverse math functions
- `atan2(Y, X)`  [page 188] Diverse math functions
- `sinh(X)`  [page 188] Diverse math functions
- `cosh(X)`  [page 188] Diverse math functions
- `tanh(X)`  [page 188] Diverse math functions
- `asinh(X)`  [page 188] Diverse math functions
- `acosh(X)`  [page 188] Diverse math functions
- `atanh(X)`  [page 188] Diverse math functions
- `exp(X)`  [page 188] Diverse math functions
- `log(X)`  [page 188] Diverse math functions
- `log10(X)`  [page 188] Diverse math functions
- `pow(X, Y)`  [page 188] Diverse math functions
- `sqrt(X)`  [page 188] Diverse math functions
- `erf(X)` -> `float()`  [page 188] Error function.
- `erfc(X)` -> `float()`  [page 189] Another error function
ms_transform

The following functions are exported:

- `parse_transform(Forms, Options) -> Forms`
  [page 192] Transforms erlang abstract format containing calls to ets/dbg:fun2ms into literal match specifications.

- `transform_from_shell(Dialect, Clauses, BoundEnvironment) -> term()`
  [page 192] Used when transforming fun's created in the shell into match specifications.

- `format_error(Errcode) -> ErrMessage`
  [page 192] Error formatting function as required by the parse_transform interface.

orddict

No functions are exported.

ordsets

No functions are exported.

pg

The following functions are exported:

- `create(PgName)`
  [page 195] Create an empty group

- `create(PgName, Node)`
  [page 195] Create an empty group on a node

- `join(PgName, Pid)`
  [page 195] Join a Pid to a process group

- `send(Pgname, Message)`
  [page 195] Send a message tuple to all members of a process group

- `esend(PgName, Mess)`
  [page 195] Send a message tuple to all members of a process group except the current node

- `members(PgName)`
  [page 195] Return a list of the current members in the process group
pool

The following functions are exported:

- `start(Name)`  
  [page 196] > Start a new pool
- `start(Name, Args)`  
  [page 196] > Start a new pool
- `attach(Node)`  
  [page 196] Ensure that a pool master is running
- `stop()`  
  [page 196] Stop the pool and kill all the slave nodes
- `get_nodes()`  
  [page 197] Return a list of the current member nodes of the pool
- `pspawn(Mod, Fun, Args)`  
  [page 197] Spawn a process on the expected lowest future loaded pool node
- `pspawn_link(Mod, Fun, Args)`  
  [page 197] Spawn links a process on the expected lowest future loaded pool node
- `get_node()`  
  [page 197] Return the node ID of the expected lowest future loaded node
- `new_node(Host, Name)`  
  [page 197] Start a new node and attach it to an already existing pool

proc_lib

The following functions are exported:

- `spawn(Module, Func, Args) -> Pid`  
  [page 198] Spawn a new process
- `spawn(Node, Module, Func, Args) -> Pid`  
  [page 198] Spawn a new process
- `spawn_link(Module, Func, Args) -> Pid`  
  [page 198] Spawn a new process and sets a link
- `spawn_link(Node, Module, Func, Args) -> Pid`  
  [page 198] Spawn a new process and sets a link
- `spawn_opt(Module, Func, Args,Opts) -> Pid`  
  [page 199] Spawn a new process with given options
- `start(Module, Func, Args) -> Ret`  
  [page 199] Start a new process synchronously
- `start(Module, Func, Args,Time) -> Ret`  
  [page 199] Start a new process synchronously
- `start(Module, Func, Args,Time,SpawnOpt) -> Ret`  
  [page 199] Start a new process synchronously
- `start_link(Module, Func, Args) -> Ret`  
  [page 199] Start a new process synchronously
- `start_link(Module, Func, Args,Time) -> Ret`  
  [page 199] Start a new process synchronously
- `start_link(Module, Func, Args, Time, SpawnOpts) -> Ret`
  [page 199] Start a new process synchronously
- `init_ack(Parent, Ret) -> void()`
  [page 199] Used by a process when it has started
- `init_ack(Ret) -> void()`
  [page 199] Used by a process when it has started
- `format(CrashReport) -> string()`
  [page 200] Format a crash report
- `initial_call(PidOrPinfo) -> {Module, Function, Args} | false`
  [page 200] Extract the initial call of a proc_lib spawned process
- `translate_initial_call(PidOrPinfo) -> {Module, Function, Arity}`
  [page 200] Extract and translate the initial call of a proc_lib spawned process

proplists

The following functions are exported:

- `append_values(Key, List) -> List`
  [page 202]
- `compact(List) -> List`
  [page 202]
- `delete(Key, List) -> List`
  [page 202]
- `expand(Expansions, List) -> List`
  [page 202]
- `get_all_values(Key, List) -> [term()]`
  [page 203]
- `get_bool(Key, List) -> bool()`
  [page 203]
- `get_keys(List) -> [term()]`
  [page 203]
- `get_value(Key, List) -> term()`
  [page 204]
- `get_value(Key, List, Default) -> term()`
  [page 204]
- `is_defined(Key, List) -> bool()`
  [page 204]
- `lookup(Key, List) -> none | tuple()`
  [page 204]
- `lookup_all(Key, List) -> [tuple()]`
  [page 204]
- `normalize(List, Stages) -> List`
  [page 204]
- `property(Property) -> Property`
  [page 205]
- `property(Key, Value) -> Property`
  [page 205]
• substitute_aliases(Aliases, List) -> List [page 205]
• substitute_negations(Negations, List) -> List [page 206]
• unfold(List) -> List [page 206]

queue

The following functions are exported:

• new() -> Queue [page 207] Create a new empty FIFO queue
• in(Item, Q1) -> Q2 [page 207] Insert an item into a queue
• out(Q) -> Result [page 207] Remove an item from a queue
• to_list(Q) -> list() [page 207] Convert a queue to a list

random

The following functions are exported:

• seed() -> ran() [page 208] Seeds random number generation with default values
• seed(A1, A2, A3) -> ran() [page 208] Seeds random number generator
• seed0() -> ran() [page 208] Return default state for random number generation
• uniform() -> float() [page 208] Return a random float
• uniform(N) -> int() [page 208] Return a random integer
• uniform(State0) -> {float(), State1} [page 209] Return a random float
• uniform(N, State0) -> {int(), State1} [page 209] Return a random integer
regexp

The following functions are exported:

- `match(String, RegExp) -> MatchRes`
  [page 210] Match a regular expression
- `first_match(String, RegExp) -> MatchRes`
  [page 210] Match a regular expression
- `matches(String, RegExp) -> MatchRes`
  [page 210] Match a regular expression
- `sub(String, RegExp, New) -> SubRes`
  [page 211] Substitute the first occurrence of a regular expression
- `gsub(String, RegExp, New) -> SubRes`
  [page 211] Substitute all occurrences of a regular expression
- `split(String, RegExp) -> SplitRes`
  [page 211] Split a string into fields
- `sh_to_awk(ShRegExp) -> AwkRegExp`
  [page 212] Convert an sh regular expression into an AWK one
- `parse(RegExp) -> ParseRes`
  [page 212] Parse a regular expression
- `format_error(ErrorDescriptor) -> string()`
  [page 212] Format an error descriptor

sets

The following functions are exported:

- `new() -> Set`
  [page 215] Return an empty set
- `is_set(Set) -> bool()`
  [page 215] Test for an Set
- `size(Set) -> int()`
  [page 215] Return the number of elements in a set
- `to_list(Set) -> List`
  [page 215] Convert an Set into a list
- `from_list(List) -> Set`
  [page 215] Convert a list into an Set
- `is_element(Element, Set) -> bool()`
  [page 215] Test for membership of an Set
- `add_element(Element, Set1) -> Set2`
  [page 216] Add an element to an Set
- `del_element(Element, Set1) -> Set2`
  [page 216] Remove an element from an Set
- `union(Set1, Set2) -> Set3`
  [page 216] Return the union of two Sets
- `union(SetList) -> Set`
  [page 216] Return the union of a list of Sets
- intersection(Set1, Set2) -> Set3
  [page 216] Return the intersection of two Sets
- intersection(SetList) -> Set
  [page 216] Return the intersection of a list of Sets
- subtract(Set1, Set2) -> Set3
  [page 216] Return the difference of two Sets
- is_subset(Set1, Set2) -> bool()
  [page 217] Test for subset
- fold(Function, Acc0, Set) -> Acc1
  [page 217] Fold over set elements
- filter(Pred, Set1) -> Set2
  [page 217] Filter set elements

shell

The following functions are exported:

- history(N) -> integer()
  [page 224] Sets the number of previous commands to keep
- results(N) -> integer()
  [page 224] Sets the number of previous commands to keep

shell_default

No functions are exported.

slave

The following functions are exported:

- start(Host)
  [page 226] Start a slave node at Host
- start_link(Host)
  [page 226] Start a slave node at Host
- start(Host, Name)
  [page 226] Start a slave node at Host called Name@Host
- start_link(Host, Name)
  [page 227] Start a slave node at Host called Name@Host
- start(Host, Name, Args) -> {ok, Node} | {error, ErrorInfo}
  [page 227] Start a slave node at Host called Name@Host and passes Args to new node
- start_link(Host, Name, Args)
  [page 227] Start a slave node at Host called Name@Host
- stop(Node)
  [page 228] Stop (kill) a node
- pseudo([Master | ServerList])
  [page 228] Start a number of pseudo servers
• pseudo(Master, ServerList)
  [page 228] Start a number of pseudo servers
• relay(Pid)
  [page 228] Run a pseudo server

sofs

The following functions are exported:

• a_function(Tuples [, Type]) -> Function
  [page 232] Create a function.
• canonical_relation(SetOfSets) -> BinRel
  [page 233] Return the canonical map.
• composite(Function1, Function2) -> Function3
  [page 233] Return the composite of two functions.
• constant_function(Set, AnySet) -> Function
  [page 233] Create the function that maps each element of a set onto another set.
• converse(BinRel1) -> BinRel2
  [page 233] Return the converse of a binary relation.
• difference(Set1, Set2) -> Set3
  [page 234] Return the difference of two sets.
• digraph_to_family(Graph [, Type]) -> Family
  [page 234] Create a family from a directed graph.
• domain(BinRel) -> Set
  [page 234] Return the domain of a binary relation.
• drestriction(BinRel1, Set) -> BinRel2
  [page 234] Return a restriction of a binary relation.
• drestriction(SetFun, Set1, Set2) -> Set3
  [page 235] Return a restriction of a relation.
• empty_set() -> Set
  [page 235] Return the untyped empty set.
• extension(BinRel1, Set, AnySet) -> BinRel2
  [page 235] Extend the domain of a binary relation.
• family(Tuples [, Type]) -> Family
  [page 235] Create a family of subsets.
• family_difference(Family1, Family2) -> Family3
  [page 236] Return the difference of two families.
• family_domain(Family1) -> Family2
  [page 236] Return a family of domains.
• family_field(Family1) -> Family2
  [page 236] Return a family of fields.
• family_intersection(Family1) -> Family2
  [page 236] Return the intersection of a family of sets of sets.
• family_intersection(Family1, Family2) -> Family3
  [page 237] Return the intersection of two families.
• family_projection(SetFun, Family1) -> Family2
  [page 237] Return a family of modified subsets.
- `family_range(Family1) -> Family2`
  [page 237] Return a family of ranges.
- `family_specification(Fun, Family1) -> Family2`
  [page 237] Select a subset of a family using a predicate.
- `family_to_graph(Family [, GraphType]) -> Graph`
  [page 238] Create a directed graph from a family.
- `family_to_relation(Family) -> BinRel`
  [page 238] Create a binary relation from a family.
- `family_union(Family1) -> Family2`
  [page 238] Return the union of a family of sets of sets.
- `family_union(Family1, Family2) -> Family3`
  [page 239] Return the union of two families.
- `field(BinRel) -> Set`
  [page 239] Return the field of a binary relation.
- `from_external(ExternalSet, Type) -> AnySet`
  [page 239] Create a set.
- `from_sets(ListOfSets) -> Set`
  [page 239] Create a set out of a list of sets.
- `from_sets(TupleOfSets) -> Ordset`
  [page 239] Create an ordered set out of a tuple of sets.
- `from_term(Term [, Type]) -> AnySet`
  [page 240] Create a set.
- `image(BinRel, Set1) -> Set2`
  [page 240] Return the image of a set under a binary relation.
- `intersection(SetOfSets) -> Set`
  [page 241] Return the intersection of a set of sets.
- `intersection(Set1, Set2) -> Set3`
  [page 241] Return the intersection of two sets.
- `intersection_of_family(Family) -> Set`
  [page 241] Return the intersection of a family.
- `inverse(Function1) -> Function2`
  [page 241] Return the inverse of a function.
- `inverse_image(BinRel, Set1) -> Set2`
  [page 241] Return the inverse image of a set under a binary relation.
- `is_a_function(BinRel) -> Bool`
  [page 242] Test for a function.
- `is_disjoint(Set1, Set2) -> Bool`
  [page 242] Test for disjoint sets.
- `is_empty_set(AnySet) -> Bool`
  [page 242] Test for an empty set.
- `is_equal(AnySet1, AnySet2) -> Bool`
  [page 242] Test two sets for equality.
- `is_set(AnySet) -> Bool`
  [page 242] Test for an unordered set.
- `is_software_set(Term) -> Bool`
  [page 242] Test for an unordered set.
- `is_subset(Set1, Set2) -> Bool`  
  [page 243] Test two sets for subset.
- `is_type(Term) -> Bool`  
  [page 243] Test for a type.
- `join(Relation1, I, Relation2, J) -> Relation3`  
  [page 243] Return the join of two relations.
- `multiple_relative_product(TupleOfBinRels, BinRel1) -> BinRel2`  
  [page 243] Return the multiple relative product of a tuple of binary relations and a relation.
- `no_elements(ASet) -> NoElements`  
  [page 243] Return the number of elements of a set.
- `partition(SetOfSets) -> Partition`  
  [page 244] Return the coarsest partition given a set of sets.
- `partition(SetFun, Set) -> Partition`  
  [page 244] Return a partition of a set.
- `partition(SetFun, Set1, Set2) -> {Set3, Set4}`  
  [page 244] Return a partition of a set.
- `partition_family(SetFun, Set) -> Family`  
  [page 244] Return a family indexing a partition.
- `product(TupleOfSets) -> Relation`  
  [page 245] Return the Cartesian product of a tuple of sets.
- `product(Set1, Set2) -> BinRel`  
  [page 245] Return the Cartesian product of two sets.
- `projection(SetFun, Set1) -> Set2`  
  [page 245] Return a set of substituted elements.
- `range(BinRel) -> Set`  
  [page 246] Return the range of a binary relation.
- `relation(Tuples [, Type]) -> Relation`  
  [page 246] Create a relation.
- `relation_to_family(BinRel) -> Family`  
  [page 246] Create a family from a binary relation.
- `relative_product(TupleOfBinRels [, BinRel1]) -> BinRel2`  
  [page 246] Return the relative product of a tuple of binary relations and a binary relation.
- `relative_product(BinRel1, BinRel2) -> BinRel3`  
  [page 246] Return the relative product of two binary relations.
- `relative_product1(BinRel1, BinRel2) -> BinRel3`  
  [page 247] Return the relative product of two binary relations.
- `restriction(BinRel1, Set) -> BinRel2`  
  [page 247] Return a restriction of a binary relation.
- `restriction(SetFun, Set1, Set2) -> Set3`  
  [page 248] Return a restriction of a set.
- `set(Terms [, Type]) -> Set`  
  [page 248] Create a set of atoms or any type of sets.
- `specification(Fun, Set1) -> Set2`  
  [page 248] Select a subset using a predicate.
- `strict_relation(BinRel1) -> BinRel2`  
  [page 248] Return the strict relation corresponding to a given relation.

- `substitution(SetFun, Set1) -> Set2`  
  [page 248] Return a function with a given set as domain.

- `symdiff(Set1, Set2) -> Set3`  
  [page 249] Return the symmetric difference of two sets.

- `symmetric_partition(Set1, Set2) -> {Set3, Set4, Set5}`  
  [page 250] Return a partition of two sets.

- `to_external(AnySet) -> ExternalSet`  
  [page 250] Return the elements of a set.

- `to_sets(ASet) -> Sets`  
  [page 250] Return a list or a tuple of the elements of set.

- `type(AnySet) -> Type`  
  [page 250] Return the type of a set.

- `union(SetOfSets) -> Set`  
  [page 250] Return the union of a set of sets.

- `union(Set1, Set2) -> Set3`  
  [page 250] Return the union of two sets.

- `union_of_family(Family) -> Set`  
  [page 250] Return the union of a family.

- `weak_relation(BinRel1) -> BinRel2`  
  [page 251] Return the weak relation corresponding to a given relation.

**string**

The following functions are exported:

- `len(String) -> Length`  
  [page 252] Return the length of a string

- `equal(String1, String2) -> bool()`  
  [page 252] Test string equality

- `concat(String1, String2) -> String3`  
  [page 252] Concatenate two strings

- `chr(String, Character) -> Index`  
  [page 252] Return the index of the first/last occurrence of Character in String

- `rchr(String, Character) -> Index`  
  [page 252] Return the index of the first/last occurrence of Character in String

- `str(String, SubString) -> Index`  
  [page 252] Find the index of a substring

- `rstr(String, SubString) -> Index`  
  [page 252] Find the index of a substring

- `span(String, Chars) -> Length`  
  [page 253] Span characters at start of string

- `cspan(String, Chars) -> Length`  
  [page 253] Span characters at start of string

- `substr(String, Start) -> SubString`  
  [page 253] Return a substring of String
- `substr(String, Start, Length) -> Substring` [page 253] Return a substring of String
- `tokens(String, SeparatorList) -> Tokens` [page 253] Split string into tokens
- `chars(Character, Number) -> String` [page 253] Returns a string consisting of numbers of characters
- `chars(Character, Number, Tail) -> String` [page 253] Returns a string consisting of numbers of characters
- `copies(String, Number) -> Copies` [page 254] Copy a string
- `words(String) -> Count` [page 254] Count blank separated words
- `words(String, Character) -> Count` [page 254] Count blank separated words
- `subword(String, Number) -> Word` [page 254] Extract subword
- `subword(String, Number, Character) -> Word` [page 254] Extract subword
- `strip(String) -> Stripped` [page 254] Strip leading or trailing characters
- `strip(String, Direction) -> Stripped` [page 254] Strip leading or trailing characters
- `strip(String, Direction, Character) -> Stripped` [page 254] Strip leading or trailing characters
- `left(String, Number) -> Left` [page 255] Adjust left end of string
- `left(String, Number, Character) -> Left` [page 255] Adjust left end of string
- `right(String, Number) -> Right` [page 255] Adjust right end of string
- `right(String, Number, Character) -> Right` [page 255] Adjust right end of string
- `centre(String, Number) -> Centered` [page 255] Center a string
- `centre(String, Number, Character) -> Centered` [page 255] Center a string
- `substring(String, Start) -> SubString` [page 255] Extract a substring
- `substring(String, Start, Stop) -> SubString` [page 256] Extract a substring

**supervisor**

The following functions are exported:

- `start_link(Module, Args) -> Result` [page 259] Create a supervisor process
- \texttt{start\_link} (\texttt{SupName}, \texttt{Module}, \texttt{Args}) -> Result
  [page 259] Create a supervisor process.
- \texttt{start\_child} (\texttt{SupRef}, \texttt{ChildSpec}) -> Result
  [page 259] Dynamically add a child process to a supervisor.
- \texttt{terminate\_child} (\texttt{SupRef}, \texttt{Id}) -> Result
  [page 260] Terminate a child process belonging to a supervisor.
- \texttt{delete\_child} (\texttt{SupRef}, \texttt{Id}) -> Result
  [page 261] Delete a child specification from a supervisor.
- \texttt{restart\_child} (\texttt{SupRef}, \texttt{Id}) -> Result
  [page 261] Restart a terminated child process belonging to a supervisor.
- \texttt{which\_children} (\texttt{SupRef}) -> \{\texttt{Id,Child,Type,Modules}\}
  [page 262] Return information about all children specifications and child processes
  belonging to a supervisor.
- \texttt{check\_childspects} ([\texttt{ChildSpec}]) -> Result
  [page 262] Check if child specifications are syntactically correct.
- \texttt{Module\_init} (\texttt{Args}) -> Result
  [page 263] Return a supervisor specification.

\textbf{supervisor\_bridge}

The following functions are exported:

- \texttt{start\_link} (\texttt{Module}, \texttt{Args}) -> Result
  [page 264] Create a supervisor bridge process.
- \texttt{start\_link} (\texttt{SupBridgeName}, \texttt{Module}, \texttt{Args}) -> Result
  [page 264] Create a supervisor bridge process.
- \texttt{Module\_init} (\texttt{Args}) -> Result
  [page 265] Initialize process and start subsystem.
- \texttt{Module\_terminate} (\texttt{Reason}, \texttt{State})
  [page 265] Clean up and stop subsystem.

\textbf{sys}

The following functions are exported:

- \texttt{log} (\texttt{Name}, \texttt{Flag})
  [page 268] Log system events in memory
- \texttt{log} (\texttt{Name}, \texttt{Flag}, \texttt{Timeout}) -> \{\texttt{ok}, \texttt{[system\_event()]}\}
  [page 268] Log system events in memory
- \texttt{log\_to\_file} (\texttt{Name}, \texttt{Flag})
  [page 268] Log system events to the specified file
- \texttt{log\_to\_file} (\texttt{Name}, \texttt{Flag}, \texttt{Timeout}) -> \{\texttt{ok}, \texttt{open\_file}\}
  [page 268] Log system events to the specified file
- \texttt{statistics} (\texttt{Name}, \texttt{Flag})
  [page 268] Enable or disable the collections of statistics
- \texttt{statistics} (\texttt{Name}, \texttt{Flag}, \texttt{Timeout}) -> \{\texttt{ok}, \texttt{Statistics}\}
  [page 268] Enable or disable the collections of statistics
- `trace(Name, Flag)`
  [page 269] Print all system events on standard io
- `trace(Name, Flag, Timeout) -> void()`
  [page 269] Print all system events on standard io
- `no_debug(Name)`
  [page 269] Turn off debugging
- `no_debug(Name, Timeout) -> void()`
  [page 269] Turn off debugging
- `suspend(Name)`
  [page 269] Suspend the process
- `suspend(Name, Timeout) -> void()`
  [page 269] Suspend the process
- `resume(Name)`
  [page 269] Resume a suspended process
- `resume(Name, Timeout) -> void()`
  [page 269] Resume a suspended process
- `change_code(Name, Module, OldVsn, Extra)`
  [page 269] Send the code change system message to the process
- `change_code(Name, Module, OldVsn, Extra, Timeout) -> ok | {error, Reason}`
  [page 269] Send the code change system message to the process
- `get_status(Name)`
  [page 269] Get the status of the process
- `get_status(Name, Timeout) -> {status, Pid, {module, Mod}, [PDict, SysState, Parent, Dbg, Misc]}`
  [page 269] Get the status of the process
- `install(Name, [Func, FuncState])`  
  [page 270] Install a debug function in the process
- `install(Name, [Func, FuncState], Timeout)`  
  [page 270] Install a debug function in the process
- `remove(Name, Func)`  
  [page 270] Remove a debug function from the process
- `remove(Name, Func, Timeout) -> void()`  
  [page 270] Remove a debug function from the process
- `debug_options(Options) -> [dbg_opt()]`  
  [page 271] Convert a list of options to a debug structure
- `get_debug(Item, Debug, Default) -> term()`  
  [page 271] Get the data associated with a debug option
- `handle_debug([dbg_opt()], FormFunc, Extra, Event) -> [dbg_opt()]`  
  [page 271] Generate a system event
- `handle_system_msg(Msg, From, Parent, Module, Debug, Misc)`  
  [page 271] Take care of system messages
- `print_log(Debug) -> void()`  
  [page 272] Print the logged events in the debug structure
- `Mod:system_continue(Parent, Debug, Misc)`  
  [page 272] Called when the process should continue its execution
timer

The following functions are exported:

- Mod:system:terminate(Reason, Parent, Debug, Misc)
  [page 272] Called when the process should terminate
- Mod:system:code_change(Misc, Module, OldVsn, Extra) -> {ok, NMisc}
  [page 272] Called when the process should perform a code change

The following functions are exported:

- start() -> ok
  [page 274] Start a global timer server (named timer_server).
- apply_after(Time, Module, Function, Arguments) -> {ok, TRef} | {error, Reason}
- send_after(Time, Pid, Message) -> {ok, TRef} | {error, Reason}
  [page 274] Send Message to Pid after a specified Time.
- send_after(Time, Message) -> {ok, TRef} | {error, Reason}
  [page 274] Send Message to Pid after a specified Time.
- exit_after(Time, Pid, Reason1) -> {ok, TRef} | {error, Reason2}
  [page 275] Send an exit signal with Reason after a specified Time.
- exit_after(Time, Reason1) -> {ok, TRef} | {error, Reason2}
  [page 275] Send an exit signal with Reason after a specified Time.
- kill_after(Time, Pid) -> {ok, TRef} | {error, Reason2}
  [page 275] Send an exit signal with Reason after a specified Time.
- kill_after(Time) -> {ok, TRef} | {error, Reason2}
  [page 275] Send an exit signal with Reason after a specified Time.
- apply_interval(Time, Module, Function, Arguments) -> {ok, TRef} | {error, Reason}
- send_interval(Time, Pid, Message) -> {ok, TRef} | {error, Reason}
  [page 275] Send Message to Pid after a specified Time.
- send_interval(Time, Message) -> {ok, TRef} | {error, Reason}
  [page 275] Send Message repeatedly at intervals of Time.
- cancel(TRef) -> {ok, cancel} | {error, Reason}
  [page 275] Cancel a previously requested timeout identified by TRef.
- sleep(Time) -> ok
  [page 275] Suspend the calling process for Time amount of milliseconds.
- tc(Module, Function, Arguments) -> {Time, Value}
  [page 276] Measure the real time it takes to evaluate apply(Module, Function, Arguments)
- seconds(Seconds) ->Milliseconds
- minutes(Minutes) ->Milliseconds
  [page 276] Convert Minutes to Milliseconds.
- hours(Hours) ->Milliseconds
  [page 276] Convert Hours to Milliseconds.
- hms(Hours, Minutes, Seconds) ->Milliseconds
  [page 276] Convert Hours+Minutes+Seconds to Milliseconds.
**win32reg**

The following functions are exported:

- `change_key(RegHandle, Key) -> ReturnValue` [page 279] Move to a key in the registry.
- `change_key_create(RegHandle, Key) -> ReturnValue` [page 279] Move to a key, create it if it is not there.
- `close(RegHandle) -> ReturnValue` [page 279] Close the registry.
- `current_key(RegHandle) -> ReturnValue` [page 279] Return the path to the current key.
- `delete_key(RegHandle) -> ReturnValue` [page 279] Delete the current key.
- `delete_value(RegHandle, Name) -> ReturnValue` [page 280] Delete the named value on the current key.
- `expand(String) -> ExpandedString` [page 280] Expand a string with environment variables.
- `format_error(ErrorId) -> ErrorString` [page 280] Convert an POSIX errorcode to a string.
- `open(OpenModeList) -> ReturnValue` [page 280] Open the registry for reading or writing.
- `set_value(RegHandle, Name, Value) -> ReturnValue` [page 280] Set value at the current registry key with specified name.
- `sub_keys(RegHandle) -> ReturnValue` [page 281] Get subkeys to the current key.
- `value(RegHandle, Name) -> ReturnValue` [page 281] Get the named value on the current key.
- `values(RegHandle) -> ReturnValue` [page 281] Get all values on the current key.
beam_lib

Erlang Module

beam_lib provides an interface to files created by the BEAM compiler ("BEAM files"). The format used, a variant of "EA IFF 1985" Standard for Interchange Format Files, divides data into chunks.

Chunk data can be returned as binaries or as compound terms. Compound terms are returned when chunks are referenced by names (atoms) rather than identifiers (strings). The names recognized and the corresponding identifiers are abstract_code ("Abst"), attributes ("Attr"), exports ("ExpT"), labeled_exports ("ExpT"), imports ("ImpT"), locals ("LocT"), labeled_locals ("LocT"), and atoms ("Atom").

The syntax of the compound term (ChunkData) is as follows:

- ChunkData = {ChunkId, binary()} | {abstract_code, AbstractCode} | {attributes, [Attribute, [AttributeValue]]} | {exports, [[Function, Arity]]} | {labeled_exports, [[Function, Arity, Label]]} | {imports, [[Module, Function, Arity]]} | {locals, [[Function, Arity]]} | {labeled_locals, [[Function, Arity, Label]]}] | {atoms, [integer(), atom()]]

- ChunkRef = ChunkId | ChunkName
- ChunkName = abstract_code | attributes | exports | imports | locals
- ChunkId = string()
- AbstractCode = {AbstVersion, forms()} | no_abstract_code
- AbstVersion = atom()
- Attribute = atom()
- AttributeValue = term()
- Module = Function = atom()
- Arity = integer() >= 0
- Label = integer() >= 0

The list of attributes is sorted on Attribute, and each attribute name occurs once in the list. The attribute values occur in the same order as on the file. The lists of functions are also sorted. It is not checked that the forms conform to the abstract format indicated by AbstVersion.

no_abstract_code means that the "Abst" chunk is present, but empty.

Each of the functions described below accept either a filename or a binary containing a beam module.
Exports

chunks(FileNameOrBinary, [ChunkRef]) -> {ok, {Module, [ChunkData]}} | {error, Module, Reason}

Types:
- FileNameOrBinary = string() | atom() | binary()
- Reason = {unknown_chunk, FileName, atom()} | - see info/1 -

The `chunks/2` function reads chunk data for selected chunks. The order of the returned list of chunk data is determined by the order of the list of chunks references; if each chunk data were replaced by the tag, the result would be the given list.

version(FileNameOrBinary) -> {ok, {Module, Version}} | {error, Module, Reason}

Types:
- FileNameOrBinary = string() | atom() | binary()
- Version = [term()]
- Reason = - see chunks/2 -

The `version/1` function returns the module version(s) found in a BEAM file.

info(FileNameOrBinary) -> [SourceRef, {module, Module}, {chunks, [ChunkInfo]}] | {error, Module, Reason}

Types:
- FileName = string() | atom()
- FileNameOrBinary = FileName | binary()
- SourceRef = {file, FileName} | {binary, binary()}
- ChunkInfo = {ChunkId, StartPosition, Size}
- StartPosition = integer() > 0
- Size = integer() >= 0
- Reason = {chunk_too_big, FileName, ChunkId, ChunkSize, FileSize} |
  {invalid_beam_file, FileName, FilePosition} | {invalid_chunk, FileName, ChunkId} |
  {missing_chunk, FileName, ChunkId} | {not_a_beam_file, FileName} | {file_error, FileName, FileError}

The `info/1` function extracts some information about a BEAM file: the file name, the module name, and for each chunk the identifier as well as the position and size in bytes of the chunk data.

cmp(FileNameOrBinary, FileNameOrBinary) -> ok | {error, Module, Reason}

Types:
- FileName = string() | atom()
- FileNameOrBinary = FileName | binary()
- Reason = {modules_different, Module, Module} | {chunks_different, ChunkId} |
  - see info/1 -
The \texttt{cmp/2} function compares the contents of two BEAM files. If the module names are the same, and the chunks with the identifiers "Code", "ExpT", "ImpT", "StrT", and "Atom" have the same contents in both files, \texttt{ok} is returned. Otherwise an error message is returned.

\begin{verbatim}
\texttt{cmp\_dirs(Directory1, Directory2) -> \{Only1, Only2, Different\} | \{error, Module, Reason\}}
\end{verbatim}

Types:
\begin{itemize}
\item Directory1 = Directory2 = string() \_ atom()
\item Different = \[\{FileName1, FileName2\}\]
\item Only1 = Only2 = [FileName]
\item FileName = FileName1 = FileName2 = string()
\item Reason = - see info/1 -
\end{itemize}

The \texttt{cmp\_dirs/2} function compares the BEAM files in two directories. Only files with extension ".beam" are compared. BEAM files that exist in directory Directory1 (Directory2) only are returned in Only1 (Only2). BEAM files that exist on both directories but are considered different by \texttt{cmp/2} are returned as pairs \{FileName1, FileName2\} where FileName1 (FileName2) exists in directory Directory1 (Directory2).

\begin{verbatim}
\texttt{diff\_dirs(Directory1, Directory2) -> ok | \{error, Module, Reason\}}
\end{verbatim}

Types:
\begin{itemize}
\item Directory1 = Directory2 = string() \_ atom()
\item Reason = - see info/1 -
\end{itemize}

The \texttt{diff\_dirs/2} function compares the BEAM files in two directories the way \texttt{cmp\_dirs/2} does, but names of files that exist in only one directory or are different are present on standard output.

\begin{verbatim}
\texttt{strip\(\text{FileNameOrBinary}\) -> \{ok, \{Module, FileNameOrBinary\}\} | \{error, Module, Reason\}}
\end{verbatim}

Types:
\begin{itemize}
\item FileName = string() \_ atom()
\item FileNameOrBinary = FileName \_ binary()
\item Reason = - see info/1 -
\end{itemize}

The \texttt{strip/1} function removes all chunks from a BEAM file except those needed by the loader. In particular, the abstract code is removed. The module name found in the file and the file name, possibly with the ".beam" extension added, are returned.

\begin{verbatim}
\texttt{strip\_files(Files) -> \{ok, [[\{Module, FileNameOrBinary\}\}] | \{error, Module, Reason\}}
\end{verbatim}

Types:
\begin{itemize}
\item Files = [FileNameOrBinary]
\item FileName = string() \_ atom()
\item FileNameOrBinary = FileName \_ binary()
\item Reason = - see info/1 -
\end{itemize}
The `strip_files/1` function removes all chunks except those needed by the loader from BEAM files. In particular, the abstract code is removed. The returned list contains one element for each given file name, ordered as the given list. The list element is a pair of the module name found in the file and the file name, the latter possibly with the "beam" extension added.

```erlang
strip_release(Directory) -> {ok, [{Module, FileName}]} | {error, Module, Reason}
```

Types:
- Directory = string() | atom()
- FileName = string()
- Reason = - see info/1 -

The `strip_release/1` function removes all chunks except those needed by the loader from the BEAM files of a release. Directory should be the installation root directory. For example, the current OTP release can be stripped with the call `beam_lib:strip_release(code:root_dir())`. The returned list contains module names and file names of stripped files.

```erlang
format_error(ErrorCode) -> character_list()
```

Given the error returned by any function in this module, the function `format_error` returns a descriptive string of the error in English. For file errors, the function `format_error/1` in the `file` module is called.
C

Erlang Module

The C module enables users to enter the short form of some commonly used commands. These functions are intended for interactive use in the Erlang shell.

Exports

bt(Pid) -> void()
Types:
• Pid = pid()
This function evaluates erlang:process_display(Pid, backtrace).

c(File) -> CompileResult
This function is equivalent to:
compile:file(File, [report_errors, report_warnings])

c(File, Flags) -> CompileResult
Types:
• File = atom() | string()
• CompileResult = {ok, ModuleName} | error
• ModuleName = atom()
• Flags = [Flag]
This function calls the following function and then purges and loads the code for the file:
compile:file(File, Flags ++ [report_errors, report_warnings])
If the module corresponding to File is being interpreted, then int:i is called with the same arguments and the module is loaded into the interpreter. Note that int:i only recognizes a subset of the options recognized by compile:file. Extreme care should be exercised when using this command to change running code which is executing. The expected result may not be obtained. Refer to compiler manual pages for a description of the individual compiler flags.

cd(Dir) -> void()
Types:
• Dir = atom() | string()
This function changes the current working directory to Dir, and then prints the new working directory.

flush() -> void()
This function flushes all messages in the shell message queue.

help() -> void()
This function displays help about the shell and about the command interface module.

i() -> void()
This function provides information about the current state of the system. This call uses the BIFs processes() and process_info/1 to examine the current state of the system. (The code is a good introduction to these two BIFs).

i(X, Y, Z) -> void()
Types:
- X = Y = Z = int()
This function evaluates process_info(pid(X, Y, Z)).

l(Module) -> void()
Types:
- Module = atom() | string()
This function evaluates code:purge(Module) followed by code:load_module(Module). It reloads the module.

lc(ListOfFiles) -> Result
Types:
- ListOfFiles = [File]
- File = atom() | string()
- Result = [CompileResult]
- CompileResult = {ok, ModuleName} | error
- ModuleName = atom()
This function compiles several files by calling c(File) for each file in ListOfFiles.

ls() -> void()
This function lists all files in the current directory.

ls(Dir) -> void()
Types:
- Dir = atom() | string()
This function lists all files in the directory Dir.

m() -> void()
This function lists the modules which have been loaded and the files from which they have been loaded.

\[ m(\text{Module}) \rightarrow \text{void()} \]

Types:
- \( \text{Module} = \text{atom()} \)

This function lists information about \( \text{Module} \).

\[ \text{memory()} \rightarrow \text{TupleList} \]

Types:
- \( \text{TupleList} = [\text{TwoTuple}] \)
- \( \text{TwoTuple} = \{ \text{atom}(), \text{int}() \} \)

A list of tuples is returned. Each tuple has two elements. The first element is an atom describing memory type. The second element is memory size in bytes. A description of each tuple follows:

- **total**: The total amount of allocated memory. \( \text{total} \) is the sum of \( \text{processes} \) and \( \text{system} \).
- **processes**: The total amount of memory allocated by the processes.
- **system**: The total amount of memory allocated by the system. Memory allocated by processes is not included.
- **atom**: The total amount of memory allocated for atoms. This memory is part of the memory presented as \( \text{system} \) memory.
- **atom_used**: The total amount of memory actually used for atoms. This memory is part of the memory presented as \( \text{atom} \) memory.
- **binary**: The total amount of memory allocated for binaries. This memory is part of the memory presented as \( \text{system} \) memory.
- **code**: The total amount of memory allocated for code. This memory is part of the memory presented as \( \text{system} \) memory.
- **ets**: The total amount of memory allocated for ets tables. This memory is part of the memory presented as \( \text{system} \) memory.
- **maximum**: The maximum total amount of memory allocated since the Erlang runtime system was started.
  - This tuple is only present when the Erlang runtime system is run instrumented.

A process executing this function may be preempted by other processes; therefore, the returned information may not be a consistent snapshot of the memory allocation state. The \( \text{total} \) and \( \text{system} \) values are more accurate when the Erlang runtime system is run instrumented.

More tuples in the returned list may be added in the future.

\[ \text{memory}(\text{MemoryType}) \rightarrow \text{int()} \]
Types:
- MemoryType = atom()

MemoryType is one of the following atoms: total, processes, system, atom,
atomused, binary, code, ets, or maximum. These atoms correspond to the atoms
described for memory/0 above. The amount of memory in bytes that corresponds to the
argument is returned.

A process executing this function may be preempted by other processes; therefore, the
returned information may not be a consistent snapshot of the memory allocation state.

The total and system values are more accurate when the Erlang runtime system is run
instrumented.

More arguments may be added in the future.

Failure: badarg if MemoryType isn't one of the atoms listed above, or if the Erlang
runtime system isn't run instrumented and MemoryType is maximum.

nc(File) -> void()

Types:
- File = atom() | string()

This function compiles File and loads it on all nodes in an Erlang nodes network.

nc(File, Flags) -> void()

Types:
- File = atom() | string()
- Flags = [Flag]

This function compiles File with the additional compiler flags Flags and loads it on all
nodes in an Erlang nodes network. Refer to the compile manual pages for a description
of Flags.

ni() -> void()

This function does the same as i(), but for all nodes in the network.

nl(Module) -> void()

Types:
- Module = atom()

This function loads Module on all nodes in an Erlang nodes network.

nregs() -> void()

This function is the same as regs(), but on all nodes in the system.

pid(X, Y, Z) -> pid()

Types:
- X = Y = Z = int()

This function converts the integers X, Y, and Z to the Pid <X.Y.Z>. It saves typing and
the use of list_to_pid/1. This function should only be used when debugging.
pwd() -> void()
This function prints the current working directory.

q() -> void()
This function is shorthand for init:stop(), i.e., it causes the node to stop in a
controlled fashion.

regs() -> void()
This function displays formatted information about all registered processes in the
system.

xm(ModSpec) -> void()
Types:
- ModSpec = Module | File
- Module = atom()
- File = string()
This function finds undefined functions and unused functions in a module by calling
xref:m/1.

zi() -> void()
This function works like i(), but additionally displays information about zombie
processes, i.e., processes which have exited, but which are still kept in the system to be
inspected.

See Also
instrument(3)
This module provides computation of local and universal time, day-of-the-week, and several time conversion functions.

Time is local when it is adjusted in accordance with the current time zone and daylight saving. Time is universal when it reflects the time at longitude zero, without any adjustment for daylight saving. Universal Coordinated Time (UTC) time is also called Greenwich Mean Time (GMT).

The time functions `local_time/0` and `universal_time/0` provided in this module both return date and time. The reason for this is that separate functions for date and time may result in a date/time combination which is displaced by 24 hours. This happens if one of the functions is called before midnight, and the other after midnight. This problem also applies to the Erlang BIFs `date/0` and `time/0`, and their use is strongly discouraged if a reliable date/time stamp is required.

All dates conform to the Gregorian calendar. This calendar was introduced by Pope Gregory XIII in 1582 and was used in all Catholic countries from this year. Protestant parts of Germany and the Netherlands adopted it in 1698, England followed in 1752, and Russia in 1918 (the October revolution of 1917 took place in November according to the Gregorian calendar).

The Gregorian calendar in this module is extended back to year 0. For a given date, the gregorian days is the number of days up to and including the date specified. Similarly, the gregorian seconds for a given date and time, is the number of seconds up to and including the specified date and time.

For computing differences between epochs in time, use the functions counting gregorian days or seconds. If epochs are given as local time, they must be converted to universal time, in order to get the correct value of the elapsed time between epochs. Use of the function `time_difference/2` is discouraged.

Exports

```erlang
date_to_gregorian_days(Year, Month, Day) -> Days
date_to_gregorian_days(Date) -> Days

Types:
  - Date = {Year, Month, Day}
  - Year = Month = Day = Days = int()

This function computes the number of gregorian days starting with year 0 and ending at the given date.

datetime_to_gregorian_seconds(DateTime) -> Days
```

Erlang Module

calendar
Types:

- `DateTime = \{\text{date()}, \text{time()}\}
- `date() = \{\text{Year, Month, Day}\}
- `time() = \{\text{Hour, Minute, Second}\}
- `Year = \text{Month} = \text{Day} = \text{Hour} = \text{Minute} = \text{Second} = \text{Days} = \text{int()}`

This function computes the number of gregorian seconds starting with year 0 and ending at the given date and time.

day of the week (Date) $\rightarrow$ DayNumber
day of the week (Year, Month, Day) $\rightarrow$ DayNumber

Types:

- `Date = \{\text{Year, Month, Day}\}`
- `Year = \text{Month} = \text{Day} = \text{DayNumber} = \text{int()}`

This function computes the day of the week given Year, Month and Day. The return value denotes the day of the week as follows:

- Monday = 1, Tuesday = 2, ..., Sunday = 7

Year cannot be abbreviated and a value of 93 denotes the year 93, and not the year 1993. Month is the month number with January = 1.

Day is an integer in the range 1 and the number of days in the month Month of the year Year.

gregorian days to date (Days) $\rightarrow$ Date

Types:

- `Date = \{\text{Year, Month, Day}\}`
- `Year = \text{Month} = \text{Day} = \text{Days} = \text{int()}`

This function computes the date given the number of gregorian days.

gregorian seconds to datetime (Secs) $\rightarrow$ DateTime

Types:

- `DateTime = \{\text{date()}, \text{time()}\}
- `date() = \{\text{Year, Month, Day}\}
- `time() = \{\text{Hour, Minute, Second}\}
- `Year = \text{Month} = \text{Day} = \text{Hour} = \text{Minute} = \text{Second} = \text{Days} = \text{int()}`

This function computes the date and time from the given number of gregorian seconds.

is leap year (Year) $\rightarrow$ bool()

Types:

- `Year = \text{int()}`

This function checks if a year is a leap year.

last day of the month (Year, Month) $\rightarrow$ int()

Types:

- `Year = \text{Month} = \text{int()}`
This function computes the number of days in a month.

`local_time() -> {Date, Time}`

**Types:**
- `Date = {Year, Month, Day}`
- `Time = {Hour, Minute, Second}`
- `Year = Month = Day = Hour = Minute = Second = int()`

This function returns the local time reported by the underlying operating system.

`local_time_to_universal_time([Date, Time]) -> {Date, Time}`

**Types:**
- `Date = {Year, Month, Day}`
- `Time = {Hour, Minute, Second}`
- `Year = Month = Day = Hour = Minute = Second = int()`

This function converts from local time to Universal Coordinated Time (UTC). `Date` must refer to a local date after Jan 1, 1970.

`now_to_local_time(Now) -> {Date, Time}`

**Types:**
- `Now = {MegaSecs, Secs, MicroSecs}`
- `Date = {Year, Month, Day}`
- `Time = {Hour, Minute, Second}`
- `MegaSecs = Secs = MilliSecs = int()`
- `Year = Month = Day = Hour = Minute = Second = int()`

This function returns local date and time converted from the return value from `erlang:now()`.

`now_to_universal_time(Now) -> {Date, Time}`

`now_to_datetime(Now) -> {Date, Time}`

**Types:**
- `Now = {MegaSecs, Secs, MicroSecs}`
- `Date = {Year, Month, Day}`
- `Time = {Hour, Minute, Second}`
- `MegaSecs = Secs = MilliSecs = int()`
- `Year = Month = Day = Hour = Minute = Second = int()`

This function returns Universal Coordinated Time (UTC) converted from the return value from `erlang:now()`.

`seconds_to_daytime(Secs) -> {Days, Time}`

**Types:**
- `Time() = {Hour, Minute, Second}`
- `Hour = Minute = Second = Days = int()`
This function transforms a given number of seconds into days, hours, minutes, and seconds. The Time part is always non-negative, but Days is negative if the argument Secs is.

seconds_to_time(Secs) -> Time

Types:
- Time() = {Hour, Minute, Second}
- Hour = Minute = Second = Secs = int()

This function computes the time from the given number of seconds. Secs must be less than the number of seconds per day.

time_difference(T1, T2) -> Tdiff

Types:
- T1 = T2 = {Date, Time}
- Tdiff = {Day, {Hour, Minute, Second}}
- Date = {Year, Month, Day}
- Time = {Hour, Minute, Second}
- Year = Month = Day = Hour = Minute = Second = int()

This function returns the difference between two {Date, Time} structures. T2 should refer to an epoch later than T1.

This function is obsolete. Use the conversion functions for gregorian days and seconds instead.

time_to_seconds(Time) -> Secs

Types:
- Time() = {Hour, Minute, Second}
- Hour = Minute = Second = Secs = int()

This function computes the number of seconds since midnight up to the specified time.

universal_time() -> {Date, Time}

Types:
- Date = {Year, Month, Day}
- Time = {Hour, Minute, Second}
- Year = Month = Day = Hour = Minute = Second = int()

This function returns the Universal Coordinated Time (UTC) reported by the underlying operating system. Local time is returned if universal time is not available.

universal_time_to_local_time({Date, Time}) -> {Date, Time}

Types:
- Date = {Year, Month, Day}
- Time = {Hour, Minute, Second}
- Year = Month = Day = Hour = Minute = Second = int()
This function converts from Universal Coordinated Time (UTC) to local time. Date must refer to a date after Jan 1, 1970.

```erlang
valid_date(Date) -> bool()
valid_date(Year, Month, Day) -> bool()
```

Types:
- Date = {Year, Month, Day}
- Year = Month = Day = int()

This function checks if a date is a valid.

### Leap Years

The notion that every fourth year is a leap year is not completely true. By the Gregorian rule, a year \( Y \) is a leap year if either of the following rules is valid:

- \( Y \) is divisible by 4, but not by 100; or
- \( Y \) is divisible by 400.

Accordingly, 1996 is a leap year, 1900 is not, but 2000 is.

### Date and Time Source

Local time is obtained from the Erlang BIF `localtime/0`. Universal time is computed from the BIF `universaltime/0`.

The following facts apply:

- there are 86400 seconds in a day
- there are 365 days in an ordinary year
- there are 366 days in a leap year
- there are 1461 days in a 4 year period
- there are 36524 days in a 100 year period
- there are 146097 days in a 400 year period
- there are 719528 days between Jan 1, 0 and Jan 1, 1970.
The module `dets` provides a term storage on file. The stored terms, in this module called objects, are tuples such that one element is defined to be the key. A `Dets` table is a collection of objects with the key at the same position stored on a file.

`Dets` is used by the `Mnesia` application, and is provided as is for users who are interested in an efficient storage of `Erlang` terms on disk only. Many applications just need to store some terms in a file. `Mnesia` adds transactions, queries, and distribution. The size of `Dets` files cannot exceed 2 GB. If larger tables are needed, `Mnesia`'s table fragmentation can be used.

There are three types of `Dets` tables: set, bag and duplicate_bag. A table of type set has at most one object with a given key. If an object with a key already present in the table is inserted, the existing object is overwritten by the new object. A table of type bag has zero or more different objects with a given key. A table of type duplicate_bag has zero or more possibly equal objects with a given key.

`Dets` tables must be opened before they can be updated or read, and when finished they must be properly closed. If a table has not been properly closed, `Dets` will automatically repair the table. This can take a substantial time if the table is large. A `Dets` table is closed when the process which opened the table terminates. If several `Erlang` processes (users) open the same `Dets` table, they will share the table. The table is properly closed when all users have either terminated or closed the table. `Dets` tables are not properly closed if the `Erlang` runtime system is terminated abnormally.

**Note:**
A `^C` command abnormally terminates an `Erlang` runtime system in a `Unix` environment with a break-handler. Since all operations performed by `Dets` are disk operations, it is important to realize that a single look-up operation involves a series of disk seek and read operations. For this reason, the `Dets` functions are much slower than the corresponding `Ets` functions, although `Dets` exports a similar interface.

`Dets` organizes data as a linear hash list and the hash list grows gracefully as more data is inserted into the table. Space management on the file is performed by what is called a buddy system. The current implementation keeps the entire buddy system in RAM, which implies that if the table gets heavily fragmented, quite some memory can be used up. The only way to defragment a table is to close it and then open it again with the repair option set to force.

It is worth noting that the ordered_set type present in `Ets` is not yet implemented by `Dets`, neither is the limited support for concurrent updates which makes a sequence of first and next calls safe to use on fixed `Ets` tables. Both these features will be implemented by `Dets` in a future release of `Erlang/OTP`. Until then, the `Mnesia`
application (or some user implemented method for locking) has to be used to implement safe concurrency. Currently, no library of Erlang/OTP has support for ordered disk based term storage.

Two versions of the format used for storing objects on file are supported by Dets. The first version, 8, is the format always used for tables created by OTP R7 and earlier. The second version, 9, is the default version of tables created by OTP R8 (and later OTP releases). OTP R8 can create version 8 tables, and convert version 8 tables to version 9, and vice versa, upon request.

All Dets functions return \{error, Reason\} if an error occurs (first/1 and next/2 are exceptions, they exit the process with the error tuple). If given badly formed arguments, all functions exit the process with a badarg message.

Types

\[
\begin{align*}
\text{access}() &= \text{read} | \text{read}\_\text{write} \\
\text{auto}\_\text{save}() &= \text{infinity} | \text{int()} \\
\text{bindings}\_\text{cont}() &= \text{tuple()} \\
\text{bool}() &= \text{true} | \text{false} \\
\text{file}() &= \text{string()} \\
\text{int}() &= \text{integer()} \geq 0 \\
\text{keypos}() &= \text{integer()} \geq 1 \\
\text{name}() &= \text{atom()} | \text{ref()} \\
\text{no}\_\text{slots}() &= \text{integer()} \geq 0 | \text{default} \\
\text{object}() &= \text{tuple()} \\
\text{object}\_\text{cont}() &= \text{tuple()} \\
\text{select}\_\text{cont}() &= \text{tuple()} \\
\text{type}() &= \text{bag} | \text{duplicate}\_\text{bag} | \text{set} \\
\text{version}() &= 8 | 9 | \text{default}
\end{align*}
\]

Exports

\[
\begin{align*}
\text{all}(\text{)} &\rightarrow [\text{Name}] \\
\text{Types:} \\
&\bullet \text{Name} = \text{name()} \\
&\text{Returns a list of the names of all open tables on this node.}
\end{align*}
\]

\[
\begin{align*}
\text{bchunk}(\text{Name}, \text{Continuation}) &\rightarrow \{\text{Continuation2}, \text{Data}\} | \text{'$\text{end}\_\text{of}\_\text{table}'} | \{\text{error}, \text{Reason}\} \\
\text{Types:} \\
&\bullet \text{Name} = \text{name()} \\
&\bullet \text{Continuation} = \text{start} | \text{cont()} \\
&\bullet \text{Continuation2} = \text{cont()} \\
&\bullet \text{Data} = \text{binary()} | \text{tuple()}
\end{align*}
\]
Returns a list of objects stored in a table. The exact representation of the returned objects is not public. The lists of data can be used for initializing a table by giving the value \texttt{bchunk} to the \texttt{format} option of the \texttt{init_table/3} function. The \texttt{Mnesia} application uses this function for copying open tables. Unless the table is protected using \texttt{safe\_fixtable/2}, calls to \texttt{bchunk/2} may not work as expected if concurrent updates are made to the table.

The first time \texttt{bchunk/2} is called, an initial continuation, the atom \texttt{start}, must be provided.

The \texttt{bchunk/2} function returns a tuple \{Continuation2, Data\}, where Data is a list of objects. Continuation2 is another continuation which is to be passed on to a subsequent call to \texttt{bchunk/2}. With a series of calls to \texttt{bchunk/2} it is possible to extract all objects of the table.

\texttt{bchunk/2} returns \texttt{'$end\_of\_table'} when all objects have been returned, or \{error, Reason\} if an error occurs.

close(Name) -> ok | \{error, Reason\}
Types:
\begin{itemize}
  \item Name = name()
\end{itemize}
Closes a table. Only processes that have opened a table are allowed to close it. All open tables must be closed before the system is stopped. If an attempt is made to open a table which has not been properly closed, Dets automatically tries to repair the table.

delete(Name, Key) -> ok | \{error, Reason\}
Types:
\begin{itemize}
  \item Name = name()
\end{itemize}
Deletes all objects with the key \texttt{Key} from the table \texttt{Name}.

delete\_all\_objects(Name) -> ok | \{error, Reason\}
Types:
\begin{itemize}
  \item Name = name()
\end{itemize}
Deletes all objects from a table in almost constant time. However, if the table is fixed, \texttt{delete\_all\_objects(T)} is equivalent to \texttt{match\_delete(T, '_')}.

delete\_object(Name, Object) -> ok | \{error, Reason\}
Types:
\begin{itemize}
  \item Name = name()
  \item Object = object()
\end{itemize}
Deletes all instances of a given object from a table. If a table is of type \texttt{bag} or \texttt{duplicate\_bag}, the \texttt{delete/2} function cannot be used to delete only some of the objects with a given key. This function makes this possible.

first(Name) -> Key | \texttt{'$end\_of\_table'}
Types:
- **Key = term()**
  - **Name = name()**

Returns the first key stored in the table `Name` according to the table’s internal order, or `$end_of_table` if the table is empty.

Unless the table is protected using `safe_fixtable/2`, subsequent calls to `next/2` may not work as expected if concurrent updates are made to the table.

Should an error occur, the process is exited with an error tuple `{error, Reason}`. The reason for not returning the error tuple is that it cannot be distinguished from a key.

There are two reasons why `first/1` and `next/2` should not be used: they are not very efficient, and they prevent the use of the key `$end_of_table` since this atom is used to indicate the end of the table. If possible, the `match`, `match_object`, and `select` functions should be used for traversing tables.

**foldl**(Function, Acc0, Name) -> Acc1 | {error, Reason}

Types:
- Function = fun(Object, AccIn) -> AccOut
- Acc0 = Acc1 = AccIn = AccOut = term()
- Name = name()
- Object = object()

Calls Function on successive elements of the table `Name` together with an extra argument `AccIn`. The order in which the elements of the table are traversed is unspecified. Function must return a new accumulator which is passed to the next call. Acc0 is returned if the table is empty.

**foldr**(Function, Acc0, Name) -> Acc1 | {error, Reason}

Types:
- Function = fun(Object, AccIn) -> AccOut
- Acc0 = Acc1 = AccIn = AccOut = term()
- Name = name()
- Object = object()

Calls Function on successive elements of the table `Name` together with an extra argument `AccIn`. The order in which the elements of the table are traversed is unspecified. Function must return a new accumulator which is passed to the next call. Acc0 is returned if the table is empty.

**from_ets**(Name, EtsTab) -> ok | {error, Reason}

Types:
- Name = name()
- EtsTab = - see ets(3) -

Replaces the objects of the table `Name` with the objects of the Ets table `EtsTab`. The order in which the objects are inserted is not specified. Since `ets:safe_fixtable/2` is called, the Ets table must be public or owned by the calling process.

**info**(Name) -> InfoList | undefined

Types:
- `Name = name()`
- `InfoList = [{Item, Value}]`

Returns information about the table Name as a list of `{Item, Value}` tuples:

- `{file_size, int()}`, the size of the file in bytes.
- `{filename, file()}`, the name of the file where objects are stored.
- `{keypos, keypos()}`, the position of the key.
- `{size, int()}`, the number of objects stored in the table.
- `{type, type()}`, the type of the table.

info(Name, Item) -> Value | undefined

Types:

- `Name = name()`

Returns the information associated with Item for the table Name. In addition to the `{Item, Value}` pairs defined for info/1, the following items are allowed:

- `{access, access()}`, the access mode.
- `{auto_save, auto_save()}`, the auto save interval.
- `{hash, Hash}`. Describes which BIF is used to calculate the hash values of the objects stored in the Dets table. Possible values of Hash are `hash`, which implies that the `erlang:hash/2` BIF is used, `phash`, which implies that the `erlang:phash/2` BIF is used, and `phash2`, which implies that the `erlang:phash2/1` BIF is used.
- `{memory, int()}`, the size of the file in bytes. The same value is associated with the item `file_size`.
- `{no_keys, int()}`, the number of different keys stored in the table. Only available for version 9 tables.
- `{no_objects, int()}`, the number of objects stored in the table.
- `{no_slots, {Min, Used, Max}}`, the number of slots of the table. Min is the minimum number of slots, Used is the number of currently used slots, and Max is the maximum number of slots. Only available for version 9 tables.
- `{owner, pid()}`, the pid of the process that handles requests to the Dets table.
- `{ram_file, bool()}`, whether the table is kept in RAM.
- `{safe_fixed, SafeFixed}`. If the table is fixed, SafeFixed is a tuple `{FixedAtTime, [{Pid,RefCount}]}`. FixedAtTime is the time when the table was first fixed, and Pid is the pid of the process that fixes the table RefCount times. There may be any number of processes in the list. If the table is not fixed, SafeFixed is the atom false.
- `{version, int()}`, the version of the format of the table.

init_table(Name, InitFun [, Options]) -> ok | {error, Reason}

Types:

- `Name = atom()`
- `InitFun = fun(Arg) -> Res`
- `Arg = read | close`
- Res = end_of_input | {object()}, InitFun | {Data, InitFun} | term()
- Data = binary() | tuple()

Replaces the existing objects of the table Name with objects created by calling the input function InitFun, see below. The reason for using this function rather than calling insert/2 is that of efficiency. It should be noted that the input functions are called by the process that handles requests to the Dets table, not by the calling process.

When called with the argument read the function InitFun is assumed to return end_of_input when there is no more input, or {Objects, Fun}, where Objects is a list of objects and Fun is a new input function. Any other value Value is returned as an error {error, {init_fun, Value}}. Each input function will be called exactly once, and should an error occur, the last function is called with the argument close, the reply of which is ignored.

If the type of the table is set and there is more than one object with a given key, one of the objects is chosen. This is not necessarily the last object with the given key in the sequence of objects returned by the input functions. Extra objects should be avoided, or the file will be unnecessarily fragmented. This holds also for duplicated objects stored in tables of type duplicate_bag.

It is important that the table has a sufficient number of slots for the objects. If not, the hash list will start to grow when init_table/2 returns which will significantly slow down access to the table for a period of time. The minimum number of slots is set by the open_file/2 option min_no_slots and returned by the info/2 item no_slots. See also the min_no_slots Option below.

The Options argument is a list of {Key, Val} tuples where the following values are allowed:

- {min_no_slots, no_slots()}. Specifies the estimated number of different keys that will be stored in the table. The open_file option with the same name is ignored unless the table is created, and in that case performance can be enhanced by supplying an estimate when initializing the table.
- {format, Format}. Specifies the format of the objects returned by the function InitFun. If Format is term (the default), InitFun is assumed to return a list of tuples. If Format is bchunk, InitFun is assumed to return Data as returned by bchunk/2. This option overrides the min_no_slots option.

insert(Name, Objects) -> ok | {error, Reason}

Types:
- Name = name()
- Objects = object() | [object()]

Inserts one or more objects into the table Name. If there already exists an object with the same key as some of the given objects and the table type is set, the old object will be replaced.

is_dets_file(FileName) -> Bool | {error, Reason}

Types:
- FileName = file()
- Bool = bool()
Returns `true` if the file FileName is a Dets table, `false` otherwise.

`lookup(Name, Key) -> [Object] | {error, Reason}`

Types:
- `Key = term()`
- `Name = name()`
- `Object = object()`

Returns a list of all objects with the key `Key` stored in the table `Name`. For example:

```erlang
2> dets:open_file(abc, [{type, bag}]).
{ok,abc}
3> dets:insert(abc, {1,2,3}).
ok
4> dets:lookup(abc, {1,3,4}).
ok
5> dets:lookup(abc, 1).
[{1,2,3},{1,3,4}]
```

If the table is of type `set`, the function returns either the empty list or a list with one object, as there cannot be more than one object with a given key. If the table is of type `bag` or `duplicate_bag`, the function returns a list of arbitrary length.

Note that the order of objects returned is unspecified. In particular, the order in which objects were inserted is not reflected.

`match(Continuation) -> [{Match], Continuation2} | '$end_of_table' | {error, Reason}`

Types:
- `Continuation = Continuation2 = bindings_cont()`
- `Match = [term()]`

Matches some objects stored in a table and returns a list of the bindings that match a given pattern in some unspecified order. The table, the pattern, and the number of objects that are matched are all defined by `Continuation`, which has been returned by a prior call to `match/1` or `match/3`.

When all objects of the table have been matched, `$end_of_table` is returned.

`match(Name, Pattern) -> [Match] | {error, Reason}`

Types:
- `Name = name()`
- `Pattern = tuple()`
- `Match = [term()]`

Returns for each object of the table `Name` that matches `Pattern` a list of bindings in some unspecified order. See ets(3) [page 106] for a description of patterns. If the `keypos`th element of `Pattern` is unbound, all objects of the table are matched. If the `keypos`th element is bound, only the objects with the right key are matched.

`match(Name, Pattern, N) -> [{Match], Continuation} | '$end_of_table' | {error, Reason}`

Types:
* Name = name()
* Pattern = tuple()
* N = default | int()
* Match = [term()]
* Continuation = bindings_cont()

Matches some or all objects of the table `Name` and returns a list of the bindings that match `Pattern` in some unspecified order. See ets(3) [page 106] for a description of patterns.

A tuple of the bindings and a continuation is returned, unless the table is empty, in which case `'$end_of_table'` is returned. The continuation is to be used when matching further objects by calling `match/1`.

If the keypos'th element of `Pattern` is bound, all objects of the table are matched. If the keypos'th element is unbound, all objects of the table are matched, N objects at a time. The default, indicated by giving N the value `default`, is to let the number of objects vary depending on the sizes of the objects. If `Name` is a version 9 table, all objects with the same key are always matched at the same time which implies that more than N objects may sometimes be matched.

The table should always be protected using `safe_fixtable/2` before calling `match/3`, or errors may occur when calling `match/1`.

**match_delete(Name, Pattern) -> N | {error, Reason}**

Types:
* Name = name()
* N = int()
* Pattern = tuple()

Deletes all objects that match `Pattern` from the table `Name`, and returns the number of deleted objects. See ets(3) [page 106] for a description of patterns.

If the keypos'th element of `Pattern` is bound, only the objects with the right key are matched.

**match_object(Continuation) -> [{Object}, Continuation2] | 'end_of_table' | {error, Reason}**

Types:
* Continuation = Continuation2 = object_cont()
* Object = object()

Returns a list of some objects stored in a table that match a given pattern in some unspecified order. The table, the pattern, and the number of objects that are matched are all defined by `Continuation`, which has been returned by a prior call to `match_object/1` or `match_object/3`.

When all objects of the table have been matched, `'$end_of_table'` is returned.

**match_object(Name, Pattern) -> [Object] | {error, Reason}**

Types:
* Name = name()
* Pattern = tuple()
* Object = object()
Returns a list of all objects of the table Name that match Pattern in some unspecified order. See ets(3) [page 106] for a description of patterns.

If the keypos'th element of Pattern is unbound, all objects of the table are matched. If the keypos'th element of Pattern is bound, only the objects with the right key are matched.

Using the match_object functions for traversing all objects of a table is more efficient than calling first/1 and next/2 or slot/2.

match_object(Name, Pattern, N) -> [[Object], Continuation] | '$end of table' | {error, Reason}

Types:
- Name = name()
- Pattern = tuple()
- N = default | int()
- Object = object()
- Continuation = object_cont()

Matches some or all objects stored in the table Name and returns a list of the objects that match Pattern in some unspecified order. See ets(3) [page 106] for a description of patterns.

A list of objects and a continuation is returned, unless the table is empty, in which case '$end of table' is returned. The continuation is to be used when matching further objects by calling match_object/1.

If the keypos'th element of Pattern is bound, all objects of the table are matched. If the keypos'th element is unbound, all objects of the table are matched, N objects at a time. The default, indicated by giving N the value default, is to let the number of objects vary depending on the sizes of the objects. If Name is a version 9 table, all matching objects with the same key are always returned in the same reply which implies that more than N objects may sometimes be returned.

The table should always be protected using safe_fixtable/2 before calling match_object/3, or errors may occur when calling match_object/1.

member(Name, Key) -> Bool | {error, Reason}

Types:
- Name = name()
- Key = term()
- Bool = bool()

Works like lookup/2, but does not return the objects. The function returns true if one or more elements of the table has the key Key, false otherwise.

next(Name, Key1) -> Key2 | '$end of table'

Types:
- Name = name()
- Key1 = Key2 = term()
Returns the key following $Key1$ in the table $Name$ according to the table's internal order, or '$end_of_table' if there is no next key.
Should an error occur, the process is exited with an error tuple $\{error, Reason\}$.
Use $\text{first}/1$ to find the first key in the table.

$\text{open_file}(\text{Filename}) \to \{\text{ok, Reference}\} | \{\text{error, Reason}\}$

Types:
- $\text{FileName} = \text{file()}$
- $\text{Reference} = \text{ref()}$

Opens an existing table. If the table has not been properly closed, the error $\{error, need\_repair\}$ is returned. The returned reference is to be used as the name of the table. This function is most useful for debugging purposes.

$\text{open_file}(\text{Name}, \text{Args}) \to \{\text{ok, Name}\} | \{\text{error, Reason}\}$

Types:
- $\text{Name} = \text{atom()}$

Opens a table. An empty Dets table is created if no file exists.
The atom $\text{Name}$ is the name of the table. The table name must be provided in all subsequent operations on the table. The name can be used by other processes as well, and several process can share one table.
If two processes open the same table by giving the same name and arguments, then the table will have two users. If one user closes the table, it still remains open until the second user closes the table.
The $\text{Args}$ argument is a list of $\{\text{Key}, \text{Val}\}$ tuples where the following values are allowed:

- $\{\text{access, access()}\}$. It is possible to open existing tables in read-only mode. A table which is opened in read-only mode is not subjected to the automatic file reparation algorithm if it is later opened after a crash. The default value is $\text{read\_write}$.
- $\{\text{auto\_save, auto\_save()}\}$, the auto save interval. If the interval is an integer $\text{Time}$, the table is flushed to disk whenever it is not accessed for $\text{Time}$ milliseconds. A table that has been flushed will require no reparation when reopened after an uncontrolled emulator halt. If the interval is the atom $\text{infinity}$, auto save is disabled. The default value is 180000 (3 minutes).
- $\{\text{estimated\_no\_objects, int()}\}$. Equivalent to the $\text{min\_no\_slots}$ option.
- $\{\text{file, file()}\}$, the name of the file to be opened. The default value is the name of the table.
- $\{\text{max\_no\_slots, no\_slots()}\}$, the maximum number of slots that will be used. The default value is 2 M, and the maximal value is 32 M. Note that a higher value may increase the fragmentation of the table, and conversely, that a smaller value may decrease the fragmentation, at the expense of execution time. Only available for version 9 tables.
- $\{\text{min\_no\_slots, no\_slots()}\}$. Application performance can be enhanced with this flag by specifying, when the table is created, the estimated number of different keys that will be stored in the table. The default value as well as the minimum value is 256.
• \{keypos, keypos()\}, the position of the element of each object to be used as key. The default value is 1. The ability to explicitly state the key position is most convenient when we want to store Erlang records in which the first position of the record is the name of the record type.

• \{ram_file, bool()\}, whether the table is to be kept in RAM. Keeping the table in RAM may sound like an anomaly, but can enhance the performance of applications which open a table, insert a set of objects, and then close the table. When the table is closed, its contents are written to the disk file. The default value is false.

• \{repair, Value\}. Value can be either a bool() or the atom force. The flag specifies whether the Dets server should invoke the automatic file reparation algorithm. The default is true. If false is specified, there is no attempt to repair the file and \{error, need_repair\} is returned if the table needs to be repaired. The value force means that a reparation will take place even if the table has been properly closed. This is how to convert tables created by older versions of STD LIB. An example is tables hashed with the deprecated erlang:hash/2 BIF. Tables created with Dets from a STD LIB version of 1.8.2 and later use the erlang:phash/2 function or the erlang:phash2/1 function, which is preferred.

• \{type, type()\}, the type of the table. The default value is set.

• \{version, version()\}, the version of the format used for the table. The default value is 9. Tables on the format used before OTP R8 can be created by giving the value 8. A version 8 table can be converted to a version 9 table by giving the options \{version,9\} and \{repair,force\}.

pid2name(Pid) -> \{ok, Name\} | undefined

Types:
• Name = name()
• Pid = pid()

Returns the name of the table given the pid of a process that handles requests to a table, or undefined if there is no such table.

This function is meant to be used for debugging only.

safe_fixtable(Name, Fix)

Types:
• Name = name()
• Fix = bool()

If Fix is true, the table Name is fixed (once more) by the calling process, otherwise the table is released. The table is also released when a fixing process terminates.

If several processes fix a table, the table will remain fixed until all processes have released it or terminated. A reference counter is kept on a per process basis, and N consecutive fixes require N releases to release the table.

It is not guaranteed that calls to first/1, next/2, select and match functions work as expected even if the table has been fixed; the limited support for concurrency implemented in Ets has not yet been implemented in Dets. Fixing a table currently only disables resizing of the hash list of the table.

If objects have been added while the table was fixed, the hash list will start to grow when the table is released which will significantly slow down access to the table for a period of time.
select(Continuation) -> {Selection, Continuation2} | '$end_of_table' | {error, Reason}

Types:
- Continuation = Continuation2 = select_cont()
- Selection = [term()]

Returns the results of applying a match specification to some objects stored in a table. The table, the match specification, and the number of objects that are matched are all defined by Continuation, which has been returned by a prior call to select/1 or select/3.

When all objects of the table have been matched, '$end_of_table' is returned.

select(Name, MatchSpec) -> Selection | {error, Reason}

Types:
- Name = name()
- MatchSpec = match_spec()
- Selection = [term()]

Returns the results of applying the match specification MatchSpec to all or some objects stored in the table Name. The order of the objects is not specified. See the ERTS User's Guide for a description of match specifications.

If the keypos'th element of MatchSpec is unbound, the match specification is applied to all objects of the table. If the keypos'th element is bound, the match specification is applied to the objects with the right key(s) only.

Using the select functions for traversing all objects of a table is more efficient than calling first/1 and next/2 or slot/2.

select(Name, MatchSpec, N) -> {Selection, Continuation} | '$end_of_table' | {error, Reason}

Types:
- Name = name()
- MatchSpec = match_spec()
- N = default | int()
- Selection = [term()]
- Continuation = select_cont()

Returns the results of applying the match specification MatchSpec to some or all objects stored in the table Name. The order of the objects is not specified. See the ERTS User's Guide for a description of match specifications.

A tuple of the results of applying the match specification and a continuation is returned, unless the table is empty, in which case '$end_of_table' is returned. The continuation is to be used when matching further objects by calling select/1.

If the keypos'th element of MatchSpec is bound, the match specification is applied to all objects of the table with the right key(s). If the keypos'th element of MatchSpec is unbound, the match specification is applied to all objects of the table, N objects at a time. The default, indicated by giving N the value default, is to let the number of objects vary depending on the sizes of the objects. If Name is a version 9 table, all objects with the same key are always handled at the same time which implies that the match specification may be applied to more than N objects.
The table should always be protected using `safe_fixtable/2` before calling `select/3`, or errors may occur when calling `select/1`.

```erlang
select_delete(Name, MatchSpec) -> N | {error, Reason}

Types:
  • Name = name()
  • MatchSpec = match_spec()
  • N = int()

Deletes each object from the table `Name` such that applying the match specification `MatchSpec` to the object returns the value `true`. See the ERTS User’s Guide for a description of match specifications. Returns the number of deleted objects. If the keypos'th element of `MatchSpec` is bound, the match specification is applied to the objects with the right key(s) only.
```

```erlang
slot(Name, I) -> 'end_of_table' | [Object] | {error, Reason}

Types:
  • Name = name()
  • I = int()
  • Object = object()

The objects of a table are distributed among slots, starting with slot 0 and ending with slot n. This function returns the list of objects associated with slot I. If I is greater than n '$end_of_table' is returned.
```

```erlang
sync(Name) -> ok | {error, Reason}

Types:
  • Name = name()

Ensures that all updates made to the table `Name` are written to disk. This also applies to tables which have been opened with the `ram_file` flag set to `true`. In this case, the contents of the RAM file are flushed to disk.

Note that the space management data structures kept in RAM, the buddy system, is also written to the disk. This may take some time if the table is fragmented.
```

```erlang
to_ets(Name, EtsTab) -> EtsTab | {error, Reason}

Types:
  • Name = name()
  • EtsTab = - see ets(3) -

Inserts the objects of the Dets table `Name` into the Ets table `EtsTab`. The order in which the objects are inserted is not specified. The existing objects of the Ets table are kept unless overwritten.
```

```erlang
traverse(Name, Fun) -> Return | {error, Reason}

Types:
  • Fun = fun(Object) -> FunReturn
  • FunReturn = continue | {continue, Val} | {done, Value}
```
• \( \text{Val} = \text{Value} = \text{term()} \)
• \( \text{Name} = \text{name()} \)
• \( \text{Object} = \text{object()} \)
• \( \text{Return} = [\text{term()}] \)

Applies \( \text{Fun} \) to each object stored in the table \( \text{Name} \) in some unspecified order. Different actions are taken depending on the return value of \( \text{Fun} \). The following \( \text{Fun} \) return values are allowed:

- \text{continue} Continue to perform the traversal. For example, the following function can be used to print out the contents of a table:

  \[
  \text{fun}(\text{X}) \rightarrow \text{io:format("\text{p}-\text{n}", \[\text{X}\]), continue end.}
  \]

- \text{(continue, \text{Val})} Continue the traversal and accumulate \( \text{Val} \). The following function is supplied in order to collect all objects of a table in a list:

  \[
  \text{fun}(\text{X}) \rightarrow \{\text{continue, \text{X}}\} \text{ end.}
  \]

- \text{(done, \text{Value})} Terminate the traversal and return \( [\text{Value} \mid \text{Acc}] \).

Any other value returned by \( \text{Fun} \) terminates the traversal and is immediately returned.

\text{update\_counter(\text{Name}, \text{Key}, \text{Increment}) \rightarrow Result}

Types:
• \( \text{Name} = \text{name()} \)
• \( \text{Key} = \text{term()} \)
• \( \text{Increment} = (\text{Pos, Incr}) \mid \text{Incr} \)
• \( \text{Pos} = \text{Incr} = \text{Result} = \text{integer()} \)

Updates the object with key \( \text{Key} \) stored in the table \( \text{Name} \) of type \( \text{set} \) by adding \( \text{Incr} \) to the element at the \( \text{Pos} \)th position. The new counter value is returned. If no position is specified, the element directly following the key is updated.

This function provides a way of updating a counter, without having to look up an object, update the object by incrementing an element and insert the resulting object into the table again.

\text{See Also}

\text{ets(3) [page 106], mnesia(3)}
dict

Erlang Module

Dict implements a Key - Value dictionary. The representation of a dictionary is not defined.

Exports

append(Key, Value, Dict1) -> Dict2

Types:
- Key = Value = term()
- Dict1 = Dict2 = dictionary()

This function appends a new Value to the current list of values associated with Key. An exception is generated if the initial value associated with Key is not a list of values.

append_list(Key, ValList, Dict1) -> Dict2

Types:
- ValList = [Value]
- Key = Value = [term()]
- Dict1 = Dict2 = dictionary()

This function appends a list of values ValList to the current list of values associated with Key. An exception is generated if the initial value associated with Key is not a list of values.

erase(Key, Dict1) -> Dict2

Types:
- Key = term()
- Dict1 = Dict2 = dictionary()

This function erases all items with a given key from a dictionary.

fetch(Key, Dict) -> Value

Types:
- Key = Value = term()
- Dict = dictionary()

This function returns the value associated with Key in the dictionary Dict. fetch assumes that the Key is present in the dictionary and an exception is generated if Key is not in the dictionary.
fetch_keys(Dict) -> Keys

Types:
- Dict = dictionary()
- Keys = [term()]

This function returns a list of all keys in the dictionary.

filter(Pred, Dict1) -> Dict2

Types:
- Pred = fun(Key, Value) -> bool()
- Dict1 = Dict2 = dictionary()

Dict2 is a dictionary of all keys and values in Dict1 for which Pred(Key, Value) is true.

find(Key, Dict) -> Result

Types:
- Key = term()
- Dict = dictionary()
- Result = {ok, Value} | error

This function searches for a key in a dictionary. Returns {ok, Value} where Value is the value associated with Key, or error if the key is not present in the dictionary.

fold(Function, Acc0, Dict) -> Acc1

Types:
- Function = fun(Key, Value, AccIn) -> AccOut
- Acc0 = Acc1 = AccIn = AccOut = term()
- Dict = dictionary()

Calls Function on successive keys and values of Dict together with an extra argument Acc (short for accumulator). Function must return a new accumulator which is passed to the next call. Acc0 is returned if the list is empty. The evaluation order is undefined.

from_list(List) -> Dict

Types:
- List = [{Key, Value}]
- Dict = dictionary()

This function converts the key/value list List to a dictionary.

is_key(Key, Dict) -> bool()

Types:
- Key = term()
- Dict = dictionary()

This function tests if Key is contained in the dictionary Dict.

map(Func, Dict1) -> Dict2
Types:
- Func = fun(Key, Value) -> Value
- Dict1 = Dict2 = dictionary()

map calls Func on successive keys and values of Dict to return a new value for each key. The evaluation order is undefined.

merge(Func, Dict1, Dict2) -> Dict3

Types:
- Func = fun(Key, Value1, Value2) -> Value
- Dict1 = Dict2 = Dict3 = dictionary()

merge merges two dictionaries, Dict1 and Dict2, to create a new dictionary. All the Key - Value pairs from both dictionaries are included in the new dictionary. If a key occurs in both dictionaries then Func is called with the key and both values to return a new value. merge could be defined as:

merge(Func, D1, D2) ->
  fold(fun (K, V1, D) ->
      update(K, fun (V2) -> Func(K, V1, V2) end, V1, D)
  end, D2, D1).

but is faster.

new() -> dictionary()

This function creates a new dictionary.

store(Key, Value, Dict1) -> Dict2

Types:
- Key = Value = term()
- Dict1 = Dict2 = dictionary()

This function stores a Key - Value pair in a dictionary. If the Key already exists in Dict1, the associated value is replaced by Value.

to_list(Dict) -> List

Types:
- Dict = dictionary()
- List = [{Key, Value}]

This function converts the dictionary to a list representation.

update(Key, Function, Dict) -> Dict

Types:
- Key = term()
- Function = fun(Value) -> Value
- Dict = dictionary()

Update the a value in a dictionary by calling Function on the value to get a new value. An exception is generated if Key is not present in the dictionary.
update(Key, Function, Initial, Dict) -> Dict

Types:
- Key = Initial = term()
- Function = fun(Value) -> Value
- Dict = dictionary()

Update the a value in a dictionary by calling Function on the value to get a new value. If Key is not present in the dictionary then Initial will be stored as the first value. For example we could define append/3 as:

```erlang
append(Key, Val, D) ->
    update(Key, fun (Old) -> Old ++ [Val] end, [Val], D).
```

update_counter(Key, Increment, Dict) -> Dict

Types:
- Key = term()
- Increment = number()
- Dict = dictionary()

Add Increment to the value associated with Key and store this value. If Key is not present in the dictionary then Increment will be stored as the first value. This is could have been defined as:

```erlang
update_counter(Key, Incr, D) ->
    update(Key, fun (Old) -> Old + Incr end, Incr, D).
```

but is faster.

Notes

The functions append and append_list are included so we can store keyed values in a list accumulator. For example:

```erlang
> D0 = dict:new(),
    D1 = dict:store(files, [], D0),
    D2 = dict:append(files, f1, D1),
    D3 = dict:append(files, f2, D2),
    D4 = dict:append(files, f3, D3),
    dict:fetch(files, D4).
[f1,f2,f3]
```

This saves the trouble of first fetching a keyed value, appending a new value to the list of stored values, and storing the result.

The function fetch should be used if the key is known to be in the dictionary, otherwise find.
The digraph module implements a version of labeled directed graphs. What makes the graphs implemented here non-proper directed graphs is that multiple edges between vertices are allowed. However, the customary definition of directed graphs will be used in the text that follows.

A directed graph (or just “digraph”) is a pair \((V, E)\) of a finite set \(V\) of vertices and a finite set \(E\) of directed edges (or just “edges”). The set of edges \(E\) is a subset of \(V \times V\) (the Cartesian product of \(V\) with itself). In this module, \(V\) is allowed to be empty; the so obtained unique digraph is called the empty digraph. Both vertices and edges are represented by unique Erlang terms.

Digraphs can be annotated with additional information. Such information may be attached to the vertices and to the edges of the digraph. A digraph which has been annotated is called a labeled digraph, and the information attached to a vertex or an edge is called a label. Labels are Erlang terms.

An edge \(e = (v, w)\) is said to emanate from vertex \(v\) and to be incident on vertex \(w\). The out-degree of a vertex is the number of edges emanating from that vertex. The in-degree of a vertex is the number of edges incident on that vertex. If there is an edge emanating from \(v\) and incident on \(w\), then \(w\) is said to be an out-neighbour of \(v\), and \(v\) is said to be an in-neighbour of \(w\). A path \(P\) from \(v[1]\) to \(v[k]\) in a digraph \((V, E)\) is a non-empty sequence \(v[1], v[2], ..., v[k]\) of vertices in \(V\) such that there is an edge \((v[i], v[i+1])\) in \(E\) for \(1 \leq i < k\). The length of the path \(P\) is \(k-1\). \(P\) is simple if all vertices are distinct, except that the first and the last vertices may be the same. \(P\) is a cycle if the length of \(P\) is not zero and \(v[1] = v[k]\). A loop is a cycle of length one. A simple cycle is a path that is both a cycle and simple. An acyclic digraph is a digraph that has no cycles.

Exports

- `add_edge(G, E, V1, V2, Label) -> edge() | {error, Reason}`
- `add_edge(G, V1, V2, Label) -> edge() | {error, Reason}`
- `add_edge(G, V1, V2) -> edge() | {error, Reason}`

Types:
- `G = digraph()`
- `E = edge()`
- `V1 = V2 = vertex()`
- `Label = label()`
- `Reason = {bad_edge, Path} | {bad_vertex, V}`
- `Path = [vertex()]`
add_edge/5 creates (or modifies) the edge $E$ of the digraph $G$, using Label as the (new) label [page 76] of the edge. The edge is emanating [page 76] from $V_1$ and incident [page 76] on $V_2$. Returns $E$.

$\text{add_edge}(G, V_1, V_2, \text{Label})$ is equivalent to $\text{add_edge}(G, E, V_1, V_2, \text{Label})$, where $E$ is a created edge. Tuples on the form ['$e' | N]$, where $N$ is an integer $\geq 1$, are used for representing the created edges.

If the edge would create a cycle in an acyclic digraph [page 76], then \{error, \{bad_edge, Path\}\} is returned. If either of $V_1$ or $V_2$ is not a vertex of the digraph $G$, then \{error, \{bad_vertex, V\}\} is returned, $V = V_1$ or $V = V_2$.

$\text{add_vertex}(G, V, \text{Label}) \rightarrow \text{vertex}()$
$\text{add_vertex}(G, V) \rightarrow \text{vertex}()$
$\text{add_vertex}(G) \rightarrow \text{vertex}()$

Types:
- $G = \text{digraph}()$
- $V = \text{vertex}()$
- $\text{Label} = \text{label}()$

$\text{add_vertex}/3$ creates (or modifies) the vertex $V$ of the digraph $G$, using Label as the (new) label [page 76] of the vertex. Returns $V$.

$\text{add_vertex}(G, V, \text{Label})$ is equivalent to $\text{add_vertex}(G, V, [])$.

$\text{add_vertex}/1$ creates a vertex using the empty list as label, and returns the created vertex. Tuples on the form ['$v' | N]$, where $N$ is an integer $\geq 1$, are used for representing the created vertices.

$\text{del_edge}(G, E) \rightarrow \text{true}$

Types:
- $G = \text{digraph}()$
- $E = \text{edge}()$

Deletes the edge $E$ from the digraph $G$.

$\text{del_edges}(G, \text{Edges}) \rightarrow \text{true}$

Types:
- $G = \text{digraph}()$
- $\text{Edges} = [\text{edge}()]$

Deletes the edges in the list $\text{Edges}$ from the digraph $G$.

$\text{del_path}(G, V_1, V_2) \rightarrow \text{true}$

Types:
- $G = \text{digraph}()$
- $V_1 = V_2 = \text{vertex}()$
Deletes edges from the digraph $G$ until there are no paths \[page 76\] from the vertex $V_1$ to the vertex $V_2$.

A sketch of the procedure employed: Find an arbitrary simple path \[page 76\] $v[1], v[2], ..., v[k]$ from $V_1$ to $V_2$ in $G$. Remove all edges of $G$ emanating \[page 76\] from $v[i]$ and incident \[page 76\] to $v[i+1]$ for $1 \leq i < k$ (including multiple edges). Repeat until there is no path between $V_1$ and $V_2$.

del_vertex(G, V) \text{ -> true}

Types:
- $G = \text{digraph}()$
- $V = \text{vertex}()$

Deletes the vertex $V$ from the digraph $G$. Any edges emanating \[page 76\] from $V$ or incident \[page 76\] on $V$ are also deleted.

del_vertices(G, Vertices) \text{ -> true}

Types:
- $G = \text{digraph}()$
- Vertices = [\text{vertex}()]

Deletes the vertices in the list Vertices from the digraph $G$.

delete(G) \text{ -> true}

Types:
- $G = \text{digraph}()$

Deletes the digraph $G$. This call is important because digraphs are implemented with $Ets$. There is no garbage collection of $Ets$ tables. The digraph will, however, be deleted if the process that created the digraph terminates.

edge(G, E) \text{ -> \{E, V1, V2, Label\} | false}

Types:
- $G = \text{digraph}()$
- $E = \text{edge}()$
- $V1 = V2 = \text{vertex}()$
- $Label = \text{label}()$

Returns $\{E, V1, V2, Label\}$ where $Label$ is the label \[page 76\] of the edge $E$ emanating \[page 76\] from $V1$ and incident \[page 76\] to $V2$ of the digraph $G$. If there is no edge $E$ of the digraph $G$, then false is returned.

edges(G) \text{ -> Edges}

Types:
- $G = \text{digraph}()$
- Edges = [\text{edge}()]

Returns a list of all edges of the digraph $G$, in some unspecified order.

edges(G, V) \text{ -> Edges}
Types:
- G = digraph()
- V = vertex()
- Edges = [edge()]

Returns a list of all edges emanating from or incident on V of the digraph G, in some unspecified order.

\texttt{get\_cycle(G, V)} \rightarrow \texttt{Vertices | false}

Types:
- G = digraph()
- V\_1 = V\_2 = vertex()
- Vertices = [vertex()]

If there is a simple cycle of length two or more through the vertex V, then the cycle is returned as a list \([V, \ldots, V]\) of vertices, otherwise if there is a loop through V, then the loop is returned as a list \([V]\). If there are no cycles through V, then false is returned.

\texttt{get\_path/3} is used for finding a simple cycle through V.

\texttt{get\_path(G, V\_1, V\_2)} \rightarrow \texttt{Vertices | false}

Types:
- G = digraph()
- V\_1 = V\_2 = vertex()
- Vertices = [vertex()]

Tries to find a simple path from the vertex V\_1 to the vertex V\_2 of the digraph G. Returns the path as a list \([V\_1, \ldots, V\_2]\) of vertices, or false if no simple path from V\_1 to V\_2 of length one or more exists.

The digraph G is traversed in a depth-first manner, and the first path found is returned.

\texttt{get\_short\_cycle(G, V)} \rightarrow \texttt{Vertices | false}

Types:
- G = digraph()
- V\_1 = V\_2 = vertex()
- Vertices = [vertex()]

Tries to find an as short as possible simple cycle through the vertex V of the digraph G. Returns the cycle as a list \([V, \ldots, V]\) of vertices, or false if no simple cycle through V exists. Note that a loop through V is returned as the list \([V, V]\).

\texttt{get\_short\_path/3} is used for finding a simple cycle through V.

\texttt{get\_short\_path(G, V\_1, V\_2)} \rightarrow \texttt{Vertices | false}

Types:
- G = digraph()
- V\_1 = V\_2 = vertex()
- Vertices = [vertex()]
Tries to find an as short as possible simple path [page 76] from the vertex \( V_1 \) to the
vertex \( V_2 \) of the digraph \( G \). Returns the path as a list \([V_1, \ldots, V_2]\) of vertices, or
false if no simple path from \( V_1 \) to \( V_2 \) of length one or more exists.
The digraph \( G \) is traversed in a breadth-first manner, and the first path found is returned.

\[
\text{in\_degree}(G, V) \rightarrow \text{integer()}
\]

Types:
- \( G = \text{digraph()} \)
- \( V = \text{vertex()} \)

Returns the in-degree [page 76] of the vertex \( V \) of the digraph \( G \).

\[
\text{in\_edges}(G, V) \rightarrow \text{Edges}
\]

Types:
- \( G = \text{digraph()} \)
- \( V = \text{vertex()} \)
- \( \text{Edges} = [\text{edge()}] \)

Returns a list of all edges incident [page 76] on \( V \) of the digraph \( G \), in some unspecified
order.

\[
\text{in\_neighbours}(G, V) \rightarrow \text{Vertices}
\]

Types:
- \( G = \text{digraph()} \)
- \( V = \text{vertex()} \)
- \( \text{Vertices} = [\text{vertex()}] \)

Returns a list of all in-neighbours [page 76] of \( V \) of the digraph \( G \), in some unspecified
order.

\[
\text{info}(G) \rightarrow \text{InfoList}
\]

Types:
- \( G = \text{digraph()} \)
- \( \text{InfoList} = [\{\text{cyclicity}, \text{Cyclicity}\}, \{\text{memory}, \text{NoWords}\}, \{\text{protection}, \text{Protection}\}] \)
- \( \text{Cyclicity} = \text{cyclic} \mid \text{acyclic} \)
- \( \text{Protection} = \text{public} \mid \text{protected} \mid \text{private} \)
- \( \text{NoWords} = \text{integer()} \geq 0 \)

Returns a list of \{Tag, Value\} pairs describing the digraph \( G \). The following pairs are
returned:
- \{cyclicity, Cyclicity\}, where Cyclicity is cyclic or acyclic, according to
the options given to new.
- \{memory, NoWords\}, where NoWords is the number of words allocated to the
ets tables
- \{protection, Protection\}, where Protection is public, protected or
private, according to the options given to new.
new() \rightarrow \text{digraph()}

Equivalent to new([]).

new(Type) \rightarrow \text{digraph()} | \{\text{error}, \text{Reason}\}

Types:
- Type = [cyclic | acyclic | public | private | protected]
- Reason = \{\text{unknown_type}, \text{term()}\}

Returns an empty digraph [page 76] with properties according to the options in Type:
- cyclic: Allow cycles [page 76] in the digraph (default).
- acyclic: The digraph is to be kept acyclic [page 76].
- public: The digraph may be read and modified by any process.
- protected: Other processes can only read the digraph (default).
- private: The digraph can be read and modified by the creating process only.

If an unrecognized type option T is given, then \{\text{error}, \{\text{unknown_type}, T\}\} is returned.

\text{no_edges(G)} \rightarrow \text{integer()} \geq 0

Types:
- G = \text{digraph()}

Returns the number of edges of the digraph G.

\text{no_vertices(G)} \rightarrow \text{integer()} \geq 0

Types:
- G = \text{digraph()}

Returns the number of vertices of the digraph G.

\text{out_degree}(G, V) \rightarrow \text{integer()}

Types:
- G = \text{digraph()}
- V = \text{vertex()}

Returns the out-degree [page 76] of the vertex V of the digraph G.

\text{out_edges}(G, V) \rightarrow \text{Edges}

Types:
- G = \text{digraph()}
- V = \text{vertex()}
- Edges = [\text{edge()}]

Returns a list of all edges emanating [page 76] from V of the digraph G, in some unspecified order.

\text{out_neighbours}(G, V) \rightarrow \text{Vertices}
Types:
- \texttt{G = digraph()}
- \texttt{V = vertex()}
- \texttt{Vertices = [vertex()]}  

Returns a list of all out-neighbours [page 76] of \texttt{V} of the digraph \texttt{G}, in some unspecified order.

\texttt{vertex(G, V) -> \{V, Label\} | false}

Types:
- \texttt{G = digraph()}
- \texttt{V = vertex()}
- \texttt{Label = label()}

Returns \{\texttt{V, Label}\} where \texttt{Label} is the label [page 76] of the vertex \texttt{V} of the digraph \texttt{G}, or \texttt{false} if there is no vertex \texttt{V} of the digraph \texttt{G}.

\texttt{vertices(G) -> Vertices}

Types:
- \texttt{G = digraph()}
- \texttt{Vertices = [vertex()]}  

Returns a list of all vertices of the digraph \texttt{G}, in some unspecified order.

digraph_utils

Erlang Module

The `digraph_utils` module implements some algorithms based on depth-first traversal of directed graphs. See the `digraph` module for basic functions on directed graphs.

A directed graph (or just “digraph”) is a pair \((V, E)\) of a finite set \(V\) of vertices and a finite set \(E\) of directed edges (or just “edges”). The set of edges \(E\) is a subset of \(V \times V\) (the Cartesian product of \(V\) with itself).

Digraphs can be annotated with additional information. Such information may be attached to the vertices and to the edges of the digraph. A digraph which has been annotated is called a labeled digraph, and the information attached to a vertex or an edge is called a label.

An edge \(e = (v, w)\) is said to emanate from vertex \(v\) and to be incident on vertex \(w\). If there is an edge emanating from \(v\) and incident on \(w\), then \(w\) is said to be an out-neighbour of \(v\). A path \(P\) from \(v[1]\) to \(v[k]\) in a digraph \((V, E)\) is a non-empty sequence \(v[1], v[2], ..., v[k]\) of vertices in \(V\) such that there is an edge \((v[i], v[i+1])\) in \(E\) for \(1 \leq i < k\). The length of the path \(P\) is \(k-1\). \(P\) is a cycle if the length of \(P\) is not zero and \(v[1] = v[k]\). A loop is a cycle of length one. An acyclic digraph is a digraph that has no cycles.

A depth-first traversal of a directed digraph can be viewed as a process that visits all vertices of the digraph. Initially, all vertices are marked as unvisited. The traversal starts with an arbitrarily chosen vertex, which is marked as visited, and follows an edge to an unmarked vertex, marking that vertex. The search then proceeds from that vertex in the same fashion, until there is no edge leading to an unvisited vertex. At that point the process backtracks, and the traversal continues as long as there are unexamined edges. If there remain unvisited vertices when all edges from the first vertex have been examined, some hitherto unvisited vertex is chosen, and the process is repeated.

A partial ordering of a set \(S\) is a transitive, antisymmetric and reflexive relation between the objects of \(S\). The problem of topological sorting is to find a total ordering of \(S\) that is a superset of the partial ordering. A digraph \(G = (V, E)\) is equivalent to a relation \(E\) on \(V\) (we neglect the fact that the version of directed graphs implemented in the `digraph` module allows multiple edges between vertices). If the digraph has no cycles of length two or more, then the reflexive and transitive closure of \(E\) is a partial ordering.

A subgraph \(G'\) of \(G\) is a digraph whose vertices and edges form subsets of the vertices and edges of \(G\). \(G'\) is maximal with respect to a property \(P\) if all other subgraphs that include the vertices of \(G'\) do not have the property \(P\). A strongly connected component is a maximal subgraph such that there is a path between each pair of vertices. A connected component is a maximal subgraph such that there is a path between each pair of vertices, considering all edges undirected.
Exports

components(Digraph) -> [Component]

Types:
- Digraph = digraph()
- Component = [vertex()]

Returns a list of connected components [page 83]. Each component is represented by its vertices. The order of the vertices and the order of the components are arbitrary.
Each vertex of the digraph Digraph occurs in exactly one component.

condensation(Digraph) -> CondensedDigraph

Types:
- Digraph = CondensedDigraph = digraph()

Creates a digraph where the vertices are the strongly connected components [page 83] of Digraph as returned by strong_components/1. If X and Y are strongly connected components, and there exist vertices x and y in X and Y respectively such that there is an edge emanating [page 83] from x and incident [page 83] on y, then an edge emanating from X and incident on Y is created.
The created digraph has the same type as Digraph. All vertices and edges have the default label [page 83] [].
Each and every cycle [page 83] is included in some strongly connected component, which implies that there always exists a topological ordering [page 83] of the created digraph.

cyclic_strong_components(Digraph) -> [StrongComponent]

Types:
- Digraph = digraph()
- StrongComponent = [vertex()]

Returns a list of strongly connected components [page 83]. Each strongly component is represented by its vertices. The order of the vertices and the order of the components are arbitrary. Only vertices that are included in some cycle [page 83] in Digraph are returned, otherwise the returned list is equal to that returned by strong_components/1.

is_acyclic(Digraph) -> bool()

Types:
- Digraph = digraph()

Returns true if and only if the digraph Digraph is acyclic [page 83].

loop_vertices(Digraph) -> Vertices

Types:
- Digraph = digraph()
- Vertices = [vertex()]

Returns a list of all vertices of Digraph that are included in some loop [page 83].
postorder(Digraph) -> Vertices

Types:
- Digraph = digraph()
- Vertices = [vertex()]

Returns all vertices of the digraph Digraph. The order is given by a depth-first traversal [page 83] of the digraph, collecting visited vertices in postorder. More precisely, the vertices visited while searching from an arbitrarily chosen vertex are collected in postorder, and all those collected vertices are placed before the subsequently visited vertices.

preorder(Digraph) -> Vertices

Types:
- Digraph = digraph()
- Vertices = [vertex()]

Returns all vertices of the digraph Digraph. The order is given by a depth-first traversal [page 83] of the digraph, collecting visited vertices in pre-order.

reachable(Vertices, Digraph) -> Vertices

Types:
- Digraph = digraph()
- Vertices = [vertex()]

Returns an unsorted list of digraph vertices such that for each vertex in the list, there is a path [page 83] in Digraph from some vertex of Vertices to the vertex. In particular, since paths may have length zero, the vertices of Vertices are included in the returned list.

reachable_neighbours(Vertices, Digraph) -> Vertices

Types:
- Digraph = digraph()
- Vertices = [vertex()]

Returns an unsorted list of digraph vertices such that for each vertex in the list, there is a path [page 83] in Digraph of length one or more from some vertex of Vertices to the vertex. As a consequence, only those vertices of Vertices that are included in some cycle [page 83] are returned.

reaching(Vertices, Digraph) -> Vertices

Types:
- Digraph = digraph()
- Vertices = [vertex()]

Returns an unsorted list of digraph vertices such that for each vertex in the list, there is a path [page 83] from the vertex to some vertex of Vertices. In particular, since paths may have length zero, the vertices of Vertices are included in the returned list.

reaching_neighbours(Vertices, Digraph) -> Vertices

Types:
- \texttt{Digraph} = \texttt{digraph()}
- \texttt{Vertices} = [\texttt{vertex()}]

Returns an unsorted list of digraph vertices such that for each vertex in the list, there is a path [page 83] of length one or more from the vertex to some vertex of \texttt{Vertices}. As a consequence, only those vertices of \texttt{Vertices} that are included in some cycle [page 83] are returned.

\texttt{strong\_components(\texttt{Digraph}) -> [StrongComponent]}

Types:
- \texttt{Digraph} = \texttt{digraph()}
- \texttt{StrongComponent} = [\texttt{vertex()}]

Returns a list of strongly connected components [page 83]. Each strongly component is represented by its vertices. The order of the vertices and the order of the components are arbitrary. Each vertex of the digraph \texttt{Digraph} occurs in exactly one strong component.

\texttt{subgraph(\texttt{Digraph}, \texttt{Vertices} [, \texttt{Options}]) -> \texttt{Subgraph} | \{error, \texttt{Reason}\}}

Types:
- \texttt{Digraph} = \texttt{Subgraph} = \texttt{digraph()}
- \texttt{Options} = [{\texttt{type}, \texttt{SubgraphType}}, \{\texttt{keep}\_\texttt{labels}, \texttt{bool()}\}]
- \texttt{Reason} = \{\texttt{invalid}\_\texttt{option}, \texttt{term()}\} | \{\texttt{unknown}\_\texttt{type}, \texttt{term()}\}
- \texttt{SubgraphType} = \texttt{inherit} | \texttt{type()}
- \texttt{Vertices} = [\texttt{vertex()}]

Creates a maximal subgraph [page 83] of \texttt{Digraph} having as vertices those vertices of \texttt{Digraph} that are mentioned in \texttt{Vertices}.

If the value of the option \texttt{type} is \texttt{inherit}, which is the default, then the type of \texttt{Digraph} is used for the subgraph as well. Otherwise the option value of \texttt{type} is used as argument to \texttt{digraph:new/1}.

If the value of the option \texttt{keep}\_\texttt{labels} is \texttt{true}, which is the default, then the labels [page 83] of vertices and edges of \texttt{Digraph} are used for the subgraph as well. If the value is \texttt{false}, then the default label, [], is used for the subgraph’s vertices and edges.

\texttt{subgraph(\texttt{Digraph}, \texttt{Vertices})} is equivalent to \texttt{subgraph(\texttt{Digraph}, \texttt{Vertices}, [])}.

\texttt{topsort(\texttt{Digraph}) -> \texttt{Vertices} | \texttt{false}}

Types:
- \texttt{Digraph} = \texttt{digraph()}
- \texttt{Vertices} = [\texttt{vertex()}]

Returns a topological ordering [page 83] of the vertices of the digraph \texttt{Digraph} if such an ordering exists, \texttt{false} otherwise. For each vertex in the returned list, there are no out-neighbours [page 83] that occur earlier in the list.

\textbf{See Also}

digraph [page 76](3)
epp

Erlang Module

The Erlang code preprocessor includes functions which are used by compile to preprocess macros and include files before the actual parsing takes place.

Exports

open(FileName, IncludePath) -> {ok, Epp} | {error, ErrorDescriptor}
open(FileName, IncludePath, PredefMacros) -> {ok, Epp} | {error, ErrorDescriptor}

Types:
- FileName = atom() | string()
- IncludePath = [DirectoryName]
- DirectoryName = atom() | string()
- PredefMacros = [{atom(), term()}]
- Epp = pid() - handle to the epp server
- ErrorDescriptor = term()

Opens a file for preprocessing.

close(Epp) -> ok

Types:
- Epp = pid() - handle to the epp server
Closes the preprocessing of a file.

parse_erl_form(Epp) -> {ok, AbsForm} | {eof, Line} | {error, ErrorInfo}

Types:
- Epp = pid()
- AbsForm = term()
- Line = integer()
- ErrorInfo = see separate description below.

Returns the next Erlang form from the opened Erlang source file. The tuple {eof, Line} is returned at end-of-file. The first form corresponds to an implicit attribute -file(File,1), where File is the name of the file.

parse_file(FileName, IncludePath, PredefMacro) -> {ok, [Form]} | {error, OpenError}

Types:
- FileName = atom() | string()
Preprocesses and parses an Erlang source file. Note that the tuple \(\text{\{eof, Line\}}\) returned at end-of-file is included as a “form”.

### Error Information

The `ErrorInfo` mentioned above is the standard `ErrorInfo` structure which is returned from all IO modules. It has the following format:

\[
\text{\{ErrorLine, Module, ErrorDescriptor\}}
\]

A string which describes the error is obtained with the following call:

\[
\text{apply(Module, format_error, ErrorDescriptor)}
\]

### See Also

`erl_parse` [page 98]
erl_eval

Erlang Module

This module provides an interpreter for Erlang expressions. The expressions are in the abstract syntax as returned by erl_parse, the Erlang parser, or a call to io:parse_erl_exprs/2.

Exports

exprs(Expressions, Bindings) -> {value, Value, NewBindings}
exprs(Expressions, Bindings, LocalFunctionHandler) -> {value, Value, NewBindings}

Types:
- Expressions = as returned by erl_parse or io:parse_erl_exprs/2
- Bindings = as returned by bindings/1
- LocalFunctionHandler = {value, Func} | {eval, Func} | none

Evaluates Expressions with the set of bindings Bindings, where Expressions is a sequence of expressions (in abstract syntax) of a type which may be returned by io:parse_erl_exprs/2. See below for an explanation of how and when to use the argument LocalFunctionHandler.

Returns {value, Value, NewBindings}

expr(Expression, Bindings) -> {value, Value, NewBindings}
expr(Expression, Bindings, LocalFunctionHandler) -> {value, Value, NewBindings}

Types:
- Expression = as returned by io:parse_erl_form/2, for example
- Bindings = as returned by bindings/1
- LocalFunctionHandler = {value, Func} | {eval, Func} | none

Evaluates Expression with the set of bindings Bindings. Expression is an expression (in abstract syntax) of a type which may be returned by io:parse_erl_form/2. See below for an explanation of how and when to use the argument LocalFunctionHandler.

Returns {value, Value, NewBindings}.

expr_list(ExpressionList, Bindings) -> {ValueList, NewBindings}
expr_list(ExpressionList, Bindings, LocalFunctionHandler) -> {ValueList, NewBindings}
Evaluates a list of expressions in parallel, using the same initial bindings for each expression. Attempts are made to merge the bindings returned from each evaluation. This function is useful in the `LocalFunctionHandler`. See below.

Returns `ValueList, NewBindings`.

```erlang
new_bindings() -> BindingStruct
    Returns an empty binding structure.
```

```erlang
bindings(BindingStruct) -> Bindings
    Returns the list of bindings contained in the binding structure.
```

```erlang
binding(Name, BindingStruct) -> Binding
    Returns the binding of `Name` in `BindingStruct`.
```

```erlang
add_binding(Name, Value, Bindings) -> BindingStruct
    Adds the binding `Name = Value` to `Bindings`. Returns an updated binding structure.
```

```erlang
del_binding(Name, Bindings) -> BindingStruct
    Removes the binding of `Name` in `Bindings`. Returns an updated binding structure.
```

### Local Function Handler

During evaluation of a function, no calls can be made to local functions. An undefined function error would be generated. However, the optional argument `LocalFunctionHandler` may be used to define a function which is called when there is a call to a local function. The argument can have the following formats:

- `{value,Func}` This defines a local function handler which is called with:
  ```erlang
  Func(Name, Arguments)
  ``
  Name is the name of the local function and `Arguments` is a list of the evaluated arguments. The function handler returns the value of the local function. In this case, it is not possible to access the current bindings. To signal an error, the function handler just calls `exit/1` with a suitable exit value.

- `{eval,Func}` This defines a local function handler which is called with:
  ```erlang
  Func(Name, Arguments, Bindings)
  ``
  Name is the name of the local function, `Arguments` is a list of the unevaluated arguments, and `Bindings` are the current variable bindings. The function handler returns:
  ```erlang
  {value,Value,NewBindings}
  ``
  `Value` is the value of the local function and `NewBindings` are the updated variable bindings. In this case, the function handler must itself evaluate all the function arguments and manage the bindings. To signal an error, the function handler just calls `exit/1` with a suitable exit value.

- `none` There is no local function handler.
Bugs

The evaluator is not complete. `receive` cannot be handled properly.
Any undocumented functions in `erl_eval` should not be used.
erl_id_trans

Erlang Module

This module performs an identity parse transformation of Erlang code. It is included as an example for users who may wish to write their own parse transformers. If the option `parse_transform/2` is passed to the compiler, a user written function `parse_transform/2` is called by the compiler before the code is checked for errors.

Exports

`parse_transform(Forms, Options) -> Forms`

Types:
- `Forms = [erlang_form()]`
- `Options = [compiler_options()]`

Performs an identity transformation on Erlang forms, as an example.

Parse Transformations

Parse transformations are used if a programmer wants to use Erlang syntax, but with different semantics. The original Erlang code is then transformed into other Erlang code.

**Note:**

Programmers are strongly advised not to engage in parse transformations and no support is offered for problems encountered.

See Also

`erl_parse` [page 98] `compile`
erl_internal

Erlang Module

This module defines Erlang BIFs, guard tests and operators. This module is only of interest to programmers who manipulate Erlang code.

Exports

bif(Name, Arity) -> bool()

Types:
  • Name = atom()
  • Arity = integer()
Returns true if Name/Arity is an Erlang BIF which is automatically recognized by the compiler, otherwise false.

guard_bif(Name, Arity) -> bool()

Types:
  • Name = atom()
  • Arity = integer()
Returns true if Name/Arity is an Erlang BIF which is allowed in guards, otherwise false.

type_test(Name, Arity) -> bool()

Types:
  • Name = atom()
  • Arity = integer()
Returns true if Name/Arity is a valid Erlang type test, otherwise false.

arith_op(OpName, Arity) -> bool()

Types:
  • OpName = atom()
  • Arity = integer()
Returns true if OpName/Arity is an arithmetic operator, otherwise false.

bool_op(OpName, Arity) -> bool()

Types:
  • OpName = atom()
• Arity = integer()
  Returns true if OpName/Arity is a Boolean operator, otherwise false.

comp_op(OpName, Arity) -> bool()
Types:
• OpName = atom()
• Arity = integer()
  Returns true if OpName/Arity is a comparison operator, otherwise false.

list_op(OpName, Arity) -> bool()
Types:
• OpName = atom()
• Arity = integer()
  Returns true if OpName/Arity is a list operator, otherwise false.

send_op(OpName, Arity) -> bool()
Types:
• OpName = atom()
• Arity = integer()
  Returns true if OpName/Arity is a send operator, otherwise false.

op_type(OpName, Arity) -> Type
Types:
• OpName = atom()
• Arity = integer()
• Type = arith | bool | comp | list | send
  Returns the Type of operator that OpName/Arity belongs to, or generates a
  function_clause error if it is not an operator at all.
erl_lint

Erlang Module

This module is used to check Erlang code for illegal syntax and other bugs. It also warns against coding practices which are not recommended.

The errors detected include:

- redefined and undefined functions
- unbound and unsafe variables
- illegal record usage.

Warnings include:

- unused functions and imports
- variables imported into matches
- variables exported from if/case/receive
- variables shadowed in lambdas and list comprehensions.

Some of the warnings are optional, and can be turned on by giving the appropriate option, described below.

The functions in this module are invoked automatically by the Erlang compiler and there is no reason to invoke these functions separately unless you have written your own Erlang compiler.

Exports

module(AbsForms) -> {ok,Warnings} | {error,Errors,Warnings}
module(AbsForms, FileName) -> {ok,Warnings} | {error,Errors,Warnings}
module(AbsForms, FileName, CompileOptions) -> {ok,Warnings} | {error,Errors,Warnings}

Types:

- AbsForms = [term()]
- FileName = FileName2 = atom() | string()
- Warnings = Errors = [{Filename2,[ErrorInfo]]}
- ErrorInfo = see separate description below.
- CompileOptions = [term()]

This function checks all the forms in a module for errors. It returns:

{ok,Warnings} There were no errors in the module.
{error,Errors,Warnings} There were errors in the module.
The elements of `Options` selecting optional warnings are as follows:

```erlang
{warn_format, Verbose} Causes warnings to be emitted for malformed format strings as arguments to `io:format` and similar functions. `Verbose` selects the amount of warnings: 0 = no warnings; 1 = warnings for invalid format strings and incorrect number of arguments; 2 = warnings also when the validity could not be checked (for example, when the format string argument is a variable). The default verbosity is 1. Verbose 0 can also be selected by the option `nowarn_format`.

warn_unused_vars Causes warnings to be emitted for variables which are not used, with the exception of variables beginning with an underscore ("Prolog style warnings"). No warnings for unused variables, which is the default, can be selected by the option `nowarn_unused_vars`.

warn_export_vars Causes warnings to be emitted for all implicitly exported variables referred to after the primitives where they were first defined. No warnings for exported variables unless they are referred to in some pattern, which is the default, can be selected by the option `nowarn_export_vars`.

warn_shadow_vars Causes warnings to be emitted for "fresh" variables in functional objects or list comprehensions with the same name as some already defined variable. The default is to warn for such variables. No warnings for shadowed variables can be selected by the option `nowarn_shadow_vars`.

warn_unused_import Causes warnings to be emitted for unused imported functions. No warnings for imported functions, which is the default, can be selected by the option `nowarn_unused_import`.
```

The `AbsForms` of a module which comes from a file that is read through `epp`, the Erlang pre-processor, can come from many files. This means that any references to errors must include the file name (see `epp` [page 87], or parser `erl_parse` [page 98]). The warnings and errors returned have the following format:

```erlang
[[FileName2,[ErrorInfo]]]
```

The errors and warnings are listed in the order in which they are encountered in the forms. This means that the errors from one file may be split into different entries in the list of errors.

```erlang
is_guard_test(Expr) -> bool()
```

Types:

- `Expr = term()`

This function tests if `Expr` is a legal guard test. `Expr` is an Erlang term representing the abstract form for the expression. `erl_parse:parse_exprs(Tokens)` can be used to generate a list of `Expr`.

```erlang
format_error(ErrorDescriptor) -> string()
```

Types:

- `ErrorDescriptor = errordesc()`

Takes an `ErrorDescriptor` and returns a string which describes the error or warning. This function is usually called implicitly when processing an `ErrorInfo` structure (see below).
Error Information

The ErrorInfo mentioned above is the standard ErrorInfo structure which is returned from all IO modules. It has the following format:

    {ErrorLine, Module, ErrorDescriptor}

A string which describes the error is obtained with the following call:

apply(Module, format_error, ErrorDescriptor)

See Also

erl_parse [page 98], epp [page 87]
erl_parse

Erlang Module

This module is the basic Erlang parser which converts tokens into the abstract form of either forms (i.e., top-level constructs), expressions, or terms. Note that a token list must end with the dot token in order to be acceptable to the parse functions (see erl_scan).

Exports

parse_form(Tokens) -> {ok, AbsForm} | {error, ErrorInfo}

Types:

- Tokens = [Token]
- Token = {Tag,Line} | {Tag,Line,term()}
- Tag = atom()
- AbsForm = term()
- ErrorInfo = see section Error Information below.

This function parses Tokens as if it were a form. It returns:

- {ok, AbsForm} The parsing was successful. See section Abstract Form [page 99] below for a description of AbsForm.
- {error, ErrorInfo} An error occurred.

parse_exprs(Tokens) -> {ok, Expr_list} | {error, ErrorInfo}

Types:

- Tokens = [Token]
- Token = {Tag,Line} | {Tag,Line,term()}
- Tag = atom()
- ExprList = [AbsExpr]
- AbsExpr = term()
- ErrorInfo = see section Error Information below.

This function parses Tokens as if it were a list of expressions. It returns:

- {ok, Expr_list} The parsing was successful. Expr_list is a list of the form AbsExpr, which is described in the section Abstract Form [page 99] below.
- {error, ErrorInfo} An error occurred.

parse_term(Tokens) -> {ok, Term} | {error, ErrorInfo}
Types:
- Tokens = [Token]
- Token = {Tag,Line} | {Tag,Line,term()}
- Tag = atom()
- Term = term()
- ErrorInfo = see section Error Information below.

This function parses Tokens as if it were a term. It returns:

{ok, Term} The parsing was successful. Term is the Erlang term corresponding to the token list.
{error, ErrorInfo} An error occurred.

format_error(Errordesc) -> string()

Types:
- ErrorDescriptor = errordesc()

Uses an ErrorDescriptor and returns a string which describes the error. This function is usually called implicitly when an ErrorInfo structure is processed (see below).

tokens(AbsTerm) -> Tokens

tokens(AbsTerm, MoreTokens) -> Tokens

Types:
- Tokens = MoreTokens = [Token]
- Token = {Tag,Line} | {Tag,Line,term()}
- Tag = atom()
- AbsTerm = term()
- ErrorInfo = see section Error Information below.

This function generates a list of tokens representing the abstract form AbsTerm of an expression. Optionally, it appends Moretokens.

normalise(AbsTerm) -> Data

Types:
- AbsTerm = Data = term()

Converts the abstract form AbsTerm of a term into a conventional Erlang data structure (i.e., the term itself). This is the inverse of abstract/1.

abstract(Data) -> AbsTerm

Types:
- Data = AbsTerm = term()

Converts the Erlang data structure Data into an abstract form of type AbsTerm. This is the inverse of normalise/1.

Abstract Form

To be supplied
Error Information

The ErrorInfo mentioned above is the standard ErrorInfo structure which is returned from all IO modules. It has the format:

{ErrorLine, Module, ErrorDescriptor}

A string which describes the error is obtained with the following call:

apply(Module, format_error, ErrorDescriptor)

See Also

io [page 165], erl_scan [page 104]
The functions in this module are used to generate aesthetically attractive representations of abstract forms, which are suitable for printing. All functions return (possibly deep) lists of characters and generate an error if the form is wrong. All functions can have an optional argument which specifies a hook that is called if an attempt is made to print an unknown form.

Exports

form(Form) -> DeepCharList
form(Form, HookFunction) -> DeepCharList

Types:
- Form = term()
- HookFunction = see separate description below.
- DeepCharList = [char()] | DeepCharList

Pretty prints a Form which is an abstract form of a type which is returned by erl_parse:parse_form.

attribute(Attribute) -> DeepCharList
attribute(Attribute, HookFunction) -> DeepCharList

Types:
- Attribute = term()
- HookFunction = see separate description below.
- DeepCharList = [char()] | DeepCharList

The same as form, but only for the attribute Attribute.

function(Function) -> DeepCharList
function(Function, HookFunction) -> DeepCharList

Types:
- Function = term()
- HookFunction = see separate description below.
- DeepCharList = [char()] | DeepCharList

The same as form, but only for the function Function.

guard(Guard) -> DeepCharList
guard(Guard, HookFunction) -> DeepCharList
Types:
- Form = term()
- HookFunction = see separate description below.
- DeepCharList = \[char() | DeepCharList\]

The same as form, but only for the guard test Guard.

exprs(Expressions) -> DeepCharList
exprs(Expressions, HookFunction) -> DeepCharList
exprs(Expressions, Indent, HookFunction) -> DeepCharList

Types:
- Expressions = term()
- HookFunction = see separate description below.
- Indent = integer()
- DeepCharList = \[char() | DeepCharList\]

The same as form, but only for the sequence of expressions in Expressions.

expr(Expression) -> DeepCharList
expr(Expression, HookFunction) -> DeepCharList
expr(Expression, Indent, HookFunction) -> DeepCharList
expr(Expression, Indent, Precedence, HookFunction) -> DeepCharList

Types:
- Expression = term()
- HookFunction = see separate description below.
- Indent = integer()
- Precedence =
- DeepCharList = \[char() | DeepCharList\]

This function prints one expression. It is useful for implementing hooks (see below).

Unknown Expression Hooks

The optional argument HookFunction, shown in the functions described above, defines a function which is called when an unknown form occurs where there should be a valid expression. It can have the following formats:

Function The hook function is called by:

    Function(Expr,
             CurrentIndentation,
             CurrentPrecedence,
             HookFunction)

none There is no hook function

The called hook function should return a (possibly deep) list of characters. expr/4 is useful in a hook.

If CurrentIndentation is negative, there will be no line breaks and only a space is used as a separator.
Bugs

It should be possible to have hook functions for unknown forms at places other than expressions.

erl_scan

Erlang Module

This module contains functions for tokenizing characters into Erlang tokens.

Exports

string(CharList,StartLine) -> {ok, Tokens, EndLine} | Error
string(CharList) -> {ok, Tokens, EndLine} | Error

Types:

- CharList = string()
- StartLine = EndLine = Line = integer()
- Tokens = [{atom(),Line} | {atom(),Line,term()}]
- Error = {error, ErrorInfo, EndLine}

Takes the list of characters CharList and tries to scan (tokenize) them. Returns {ok, Tokens, EndLine}, where Tokens are the Erlang tokens from CharList. EndLine is the last line where a token was found.

StartLine indicates the initial line when scanning starts. string/1 is equivalent to string(CharList,1).

{error, ErrorInfo, EndLine} is returned if an error occurs. EndLine indicates where the error occurred.

tokens(Continuation, CharList, StartLine) -> Return

Types:

- Return = {done, Result, LeftOverChars} | {more, Continuation}
- Continuation = [] | string()
- CharList = string()
- StartLine = EndLine = integer()
- Result = {ok, Tokens, EndLine} | {eof, EndLine}
- Tokens = [{atom(),Line} | {atom(),Line,term()}]

This is the re-entrant scanner which scans characters until a dot (\'.\' whitespace) has been reached. It returns:

{done, Result, LeftOverChars} This return indicates that there is sufficient input data to get an input. Result is:

- {ok, Tokens, EndLine} The scanning was successful. Tokens is the list of tokens including dot.
- {eof, EndLine} End of file was encountered before any more tokens.
{error, ErrorInfo, EndLine} An error occurred.
{more, Continuation} More data is required for building a term. Continuation must be passed in a new call to tokens/3 when more data is available.

reserved_word(Atom) -> bool()
Returns true if Atom is an Erlang reserved word, otherwise false.

format_error(ErrorCode) -> string()
Types:
  • ErrorCode = errordesc()
Takes an ErrorCode and returns a string which describes the error or warning. This function is usually called implicitly when processing an ErrorInfo structure (see below).

Error Information

The ErrorInfo mentioned above is the standard ErrorInfo structure which is returned from all IO modules. It has the following format:

{ErrorLine, Module, ErrorCode}
A string which describes the error is obtained with the following call:
apply(Module, format_error, ErrorCode)

Notes

The continuation of the first call to the re-entrant input functions must be []. Refer to Armstrong, Virding and Williams, 'Concurrent Programming in Erlang', Chapter 13, for a complete description of how the re-entrant input scheme works.

ets

Erlang Module

This module is an interface to the Erlang built-in term storage BIFs. These provide the ability to store very large quantities of data in an Erlang runtime system, and to have constant access time to the data. (In the case of ordered_set, see below, access time is proportional to the logarithm of the number of objects stored).

Data is organized as a set of dynamic tables, which can store tuples. Each table is created by a process. When the process terminates, the table is automatically destroyed. Every table has access rights set at creation.

Tables are divided into four different types, set, ordered_set, bag and duplicate_bag. A set or ordered_set table can only have one object associated with each key. A bag or duplicate_bag can have many objects associated with each key.

The number of tables stored at one Erlang node is limited. The current default limit is approximately 1400 tables. The upper limit can be increased by setting the environment variable ERL_MAX_ETS_TABLES before starting the Erlang runtime system (i.e. with the -env option to erl/werl). The actual limit may be slightly higher than the one specified, but never lower.

Note that there is no automatic garbage collection for tables. Even if there are no references to a table from any process, it will not automatically be destroyed unless the owner process terminates. It can be destroyed explicitly by using delete/1.

Some implementation details:

- In the current implementation, every object insert and look-up operation results in one copy of the object.
- This module provides very limited support for concurrent updates. No locking is available, but the safe_fixtable/2 function can be used to guarantee that a sequence of first/1 and next/2 calls will traverse the table without errors even if another process (or the same process) simultaneously deletes or inserts objects in the table.
- 'end_of_table' should not be used as a key since this atom is used to mark the end of the table when using first/next.

In general, the functions below will exit with reason badarg if any argument is of the wrong format, or if the table identifier is invalid.

The type tid() is used to denote a table identifier. Note that the internal structure of this type is implementation-specific.
Exports

all() -> [Tab]

Types:
- Tab = tid() | atom()

Returns a list of all tables at the node. Named tables are given by their names, unnamed tables are given by their table identifiers.

delete(Tab) -> true

Types:
- Tab = tid() | atom()

Deletes the entire table Tab.

delete(Tab, Key) -> true

Types:
- Tab = tid() | atom()
- Key = term()

Deletes all objects with the key Key from the table Tab.

delete_all_objects(Tab) -> true

Types:
- Tab = tid() | atom()

Delete all objects in the ETS table Tab. The deletion is atomic.

delete_object(Tab, Object) -> true

Types:
- Tab = tid() | atom()
- Object = tuple()

Delete the exact object Object from the ETS table, leaving objects with the same key but other differences (useful for type bag).

file2tab(Filename) -> {ok,Tab} | {error,Reason}

Types:
- Filename = string() | atom()
- Tab = tid() | atom()
- Reason = term()

Reads a file produced by tab2file/2 and creates the corresponding table Tab.

first(Tab) -> Key | '$end$ of table'

Types:
- Tab = tid() | atom()
- Key = term()
Returns the first key Key in the table Tab. If the table is of the ordered_set type, the first key in Erlang term order will be returned. If the table is of any other type, the first key according to the table's internal order will be returned. If the table is empty, '$end_of_table' will be returned.

Use next/2 to find subsequent keys in the table.

```erlang
fixtable(Tab, true|false) -> true | false
Types:
  • Tab = tid() | atom()

Warning:
The function is retained for backwards compatibility only. Use safe_fixtable/2 instead.
```

Fixes a table for safe traversal. The function is primarily used by the Mnesia DBMS to implement functions which allow write operations in a table, although the table is in the process of being copied to disk or to another node. It does not keep track of when and how tables are fixed.

```erlang
foldl(Function, Acc0, Tab) -> Acc1
Types:
  • Function = fun(A, AccIn) -> AccOut
  • Tab = tid() | atom()
  • Acc0 = Acc1 = AccIn = AccOut = term()

Acc0 is returned if the table is empty. This function is similar to lists:foldl/3. The order in which the elements of the table are traversed is unspecified, except for tables of type ordered_set, for which they are traversed first to last. Since safe_fixtable/2 is called, the table must be public or owned by the calling process.

foldr(Function, Acc0, Tab) -> Acc1
Types:
  • Function = fun(A, AccIn) -> AccOut
  • Tab = tid() | atom()
  • Acc0 = Acc1 = AccIn = AccOut = term()

Acc0 is returned if the table is empty. This function is similar to lists:foldr/3. The order in which the elements of the table are traversed is unspecified, except for tables of type ordered_set, for which they are traversed last to first. Since safe_fixtable/2 is called, the table must be public or owned by the calling process.

```erlang
from_dets(Tab, DetsTab) -> Tab
Types:
  • Tab = tid() | atom()
  • DetsTab = atom()
```
Fills an already created ETS table with the objects in the already opened DETS table named DetsTab. The ETS table is emptied before the objects are inserted.

fun2ms(LiteralFun) -> MatchSpec

Types:
- LiteralFun = fun() literal
- MatchSpec = term()

Pseudo function that by means of a parse_transform translates the literal fun() typed as parameter in the function call to a match specification as described in the match_spec manual of ERTS users guide. (with literal I mean that the fun() needs to textually be written as the parameter of the function, it cannot be held in a variable which in turn is passed to the function).

The parse transform is implemented in the module ms_transform and the source must include the file ms_transform.hrl in stdlib for this pseudo function to work. Failing to include the hrl file in the source will result in a runtime error, not a compile time dito. The include file is easiest included by adding the line -include_lib("stdlib/include/ms_transform.hrl"). to the source file.

The fun() is very restricted, it can take only a single parameter (the object to match), a sole variable or a tuple. It needs to use the is_XXX guard tests and one cannot use language constructs that have no representation in a match_spec (like if, case, receive etc). The return value from the fun will be the return value of the resulting match_spec.

Example:

2> ets:fun2ms(fun({M,N}) when N > 3 -> M end).
[[{'$1','$2'},{{'>','$2',3}},{'$1'}]]

Variables from the environment can be imported, so that this works:

2> X=3.
3
3> ets:fun2ms(fun({M,N}) when N > X -> M end).
[[{'$1','$2'},{{'>' , '$2', {const,3}}},{'$1'}]]

The imported variables will be replaced by match_spec const expressions, which is consistent with the static scoping for erlang fun()'s. Local or global function calls can not be in the guard or body of the fun however. Calls to builtin match_spec functions of course is allowed:

4> ets:fun2ms(fun({M,N}) when N > X, is_atomm(M) -> M end).
{error,transform_error}

As you can see by the example, the function can be called from the shell too. The fun() needs to be literally in the call when used from the shell as well. Other means than the parse_transform are used in the shell case, but more or less the same restrictions apply (the exception being records, as they are not handled by the shell).
Warning:
If the parse_transform is not applied to a module which calls this pseudo function, the call will fail in runtime (with a badarg). The module ets actually exports a function with this name, but it should never rely be called except for when using the function in the shell. If the parse_transform is properly applied by including the ms_transform.hrl header file, compiled code will never call the function, but the function call is replaced by a literal match_spec.

More information is provided by the ms_transform manual page in stdlib.

\[ i() \rightarrow \text{void}() \]
Displays information about all ETS tables on tty.

\[ i(Tab) \rightarrow \text{void}() \]
Types:
\* Tab = tid() | atom()
Browses the table Tab on tty.

\[ \text{info(Tab)} \rightarrow \text{[(Item,Value)] | undefined} \]
Types:
\* Tab = tid() | atom()
\* Item, Value - see below
Returns information about the table Tab as a list of (Item,Value) tuples:
\* Item=memory, Value=int()
The number of words allocated to the table.
\* Item=owner, Value=pid()
The pid of the owner of the table.
\* Item=name, Value=atom()
The name of the table.
\* Item=size, Value=int()
The number of objects inserted in the table.
\* Item=node, Value=atom()
The node where the table is stored. This field is no longer meaningful as tables cannot be accessed from other nodes.
\* Item=named_table, Value=true|false
Indicates if the table is named or not.
\* Item=type, Value=set|ordered_set|bag|duplicate_bag
The table type.
\* Item=keypos, Value=int()
The key position.
\* Item=protection, Value=public|protected|private
The table access rights.
info(Tab, Item) -> Value | undefined

Types:
- Tab = tid() | atom()
- Item, Value - see below

Returns the information associated with Item for the table Tab. In addition to the \{Item,Value\} pairs defined for info/1, the following items are allowed:

- Item=fixed, Value=true|false
  Indicates if the table is fixed by any process or not.
- Item=safe\_fixed, Value={FirstFixed,Info}|false
  If the table has been fixed using safe\_fixtable/2, the call returns a tuple where FirstFixed is the time when the table was first fixed by a process, which may or may not be one of the processes it is fixed by right now. Info is a possibly empty lists of tuples \{Pid,RefCount\}, one tuple for every process the table is fixed by right now. RefCount is the value of the reference counter, keeping track of how many times the table has been fixed by the process. If the table never has been fixed, the call returns false.

init\_table(Name, InitFun) -> true

Types:
- Name = atom()
- InitFun = fun(Arg) -> Res
  Arg = read | close
  Res = end\_of\_input | [{object()}], InitFun | term()

Replaces the existing objects of the table Tab with objects created by calling the input function InitFun, see below. This function is provided for compatibility with the DETS module, it's not more efficient than filling a table by using ets:insert/2.

When called with the argument read the function InitFun is assumed to return end\_of\_input when there is no more input, or \{Objects, Fun\}, where Objects is a list of objects and Fun is a new input function. Any other value Value is returned as an error \{error, \{init\_fun, Value\}\}. Each input function will be called exactly once, and should an error occur, the last function is called with the argument close, the reply of which is ignored.

If the type of the table is set and there is more than one object with a given key, one of the objects is chosen. This is not necessarily the last object with the given key in the sequence of objects returned by the input functions. This holds also for duplicated objects stored in tables of type duplicate\_bag.

insert(Tab, ObjectOrObjects) -> true

Types:
- Tab = tid() | atom()
- ObjectOrObjects = tuple() | [tuple()]
Inserts the object or all of the objects in the list `ObjectOrObjects` into the table `Tab`. If there already exists an object with the same key as one of the objects, and the table is a `set` or `ordered_set` table, the old object will be replaced. If the list contains more than one object with the same key and the table is a `set`/`ordered_set`, one will be inserted, which one is not defined.

`last(Tab) -> Key | '$end_of_table'`

Types:
- `Tab = tid() | atom()`
- `Key = term()`

Returns the last key `Key` according to Erlang term order in the table `Tab` of the `ordered_set` type. If the table is of any other type, the function is synonymous to `first/2`. If the table is empty, `$end_of_table` is returned.

Use `prev/2` to find preceding keys in the table.

`lookup(Tab, Key) -> [Object]`

Types:
- `Tab = tid() | atom()`
- `Key = term()`
- `Object = tuple()`

Returns a list of all objects with the key `Key` in the table `Tab`.

If the table is of type `set` or `ordered_set`, the function returns either the empty list or a list with one element, as there cannot be more than one object with the same key. If the table is of type `bag` or `duplicate_bag`, the function returns a list of arbitrary length.

Note that the time order of object insertions is preserved; The first object inserted with the given key will be first in the resulting list, and so on.

Insert and look-up times in tables of type `set`, `bag` and `duplicate_bag` are constant, regardless of the size of the table. For the `ordered_set` data-type, time is proportional to the (binary) logarithm of the number of objects.

`lookup_element(Tab, Key, Pos) -> Elem`

Types:
- `Tab = tid() | atom()`
- `Key = term()`
- `Pos = int()`
- `Elem = term() | [term()]`

If the table `Tab` is of type `set` or `ordered_set`, the function returns the `Pos`th element of the object with the key `Key`.

If the table is of type `bag` or `duplicate_bag`, the functions returns a list with the `Pos`th element of every object with the key `Key`.

If no object with the key `Key` exists, the function will exit with reason `badarg`.

`match(Tab, Pattern) -> [Match]`

Types:
- `Tab = tid() | atom()`
A pattern is a term that may contain:

- bound parts (Erlang terms),
- \/ which matches any Erlang term, and
- pattern variables: \$N where \( N = 0,1,... \)

The function returns a list with one element for each matching object, where each element is an ordered list of pattern variable bindings. An example:

```erlang
ets:match(T, \$1).
```

This matches every object in the table:

- \([\text{rufsen, dog, 7}],[\text{brunte, horse, 5}],[\text{ludde, dog, 5}]\)

```erlang
ets:match(T, \$\text{\textquoteleft},\text{dog, \$1}\text{\textquoteright}).
```

```erlang
[7, 5]
```

```erlang
ets:match(T, \$\text{\textquoteleft},\text{cow, \$1}\text{\textquoteright}).
```

```erlang
[]
```

If the key is specified in the pattern, the match is very efficient. If the key is not specified, i.e. if it is a variable or an underscore, the entire table must be searched. The search time can be substantial if the table is very large.

On tables of the ordered_set type, the result is in the same order as in a first/next traversal.

```erlang
match(Tab, Pattern, Limit) -> [[Match],Continuation] | \$end_of_table'
```

Types:

- Tab = tid() \| atom()
- Pattern = tuple()
- Match = [term()]
- Continuation = term()

Works like ets:match/2 but only returns a limited \( \text{Limit} \) number of matching objects. The Continuation term can then be used in subsequent calls to ets:match/1 to get the next chunk of matching objects. This is a space efficient way to work on objects in a table which is still faster than traversing the table object by object using ets:first/1 and ets:next/1. 

\$end_of_table' is returned if the table is empty.

```erlang
match(Continuation) -> [[Match],Continuation] | \$end_of_table'
```

Types:

- Match = [term()]
- Continuation = term()

Continues a match started with ets:match/3. The next chunk of the size given in the initial ets:match/3 call is returned together with a new Continuation that can be used in subsequent calls to this function.

\$end_of_table' is returned when there are no more objects in the table.
match_delete(Tab, Pattern) -> true

Types:
- Tab = tid() | atom()
- Pattern = tuple()

Deletes all objects which match the pattern Pattern from the table Tab. See match/2 for a description of patterns.

match_object(Tab, Pattern) -> [Object]

Types:
- Tab = tid() | atom()
- Pattern = Object = tuple()

Matches the objects in the table Tab against the pattern Pattern. See match/2 for a description of patterns. The function returns a list of all objects which match the pattern.

If the key is specified in the pattern, the match is very efficient. If the key is not specified, i.e. if it is a variable or an underscore, the entire table must be searched. The search time can be substantial if the table is very large.

On tables of the ordered_set type, the result is in the same order as in a first/next traversal.

match_object(Tab, Pattern, Limit) -> {[Match],Continuation} | 'end_of_table'

Types:
- Tab = tid() | atom()
- Pattern = tuple()
- Match = [term()]
- Continuation = term()

Works like ets:match_object/2 but only returns a limited (Limit) number of matching objects. The Continuation term can then be used in subsequent calls to ets:match_object/1 to get the next chunk of matching objects. This is a space efficient way to work on objects in a table which is still faster than traversing the table object by object using ets:first/1 and ets:next/1.

'end_of_table' is returned if the table is empty.

match_object(Continuation) -> {[Match],Continuation} | 'end_of_table'

Types:
- Match = [term()]
- Continuation = term()

Continues a match started with ets:match_object/3. The next chunk of the size given in the initial ets:match_object/3 call is returned together with a new Continuation that can be used in subsequent calls to this function.

'end_of_table' is returned when there are no more objects in the table.

member(Tab, Key) -> true | false

Types:
Tab = tid() | atom()
Key = term()

Works like lookup/2, but does not return the objects. The function returns true if one or more elements in the table has the key Key, false otherwise.

new(Name, Options) -> tid()

Types:
- Name = atom()
- Options = [Option]
  - Option = Type | Access | named_table | {keypos,Pos}
- Type = set | ordered_set | bag | duplicate_bag
- Access = public | protected | private
- Pos = int()

Creates a new table and returns a table identifier which can be used in subsequent operations. The table identifier can be sent to other processes so that a table can be shared between different processes within a node.

The parameter Options is a list of atoms which specifies table type, access rights, key position and if the table is named or not. If one or more options are left out, the default values are used. This means that not specifying any options ([]) is the same as specifying [set,protected,{keypos,1}].

- set The table is a set table - one key, one object, no order among objects. This is the default table type.
- ordered_set The table is an ordered set table - one key, one object, ordered in Erlang term order, which is the order implied by the < and > operators. Tables of this type have a somewhat different behavior in some situations than tables of the other types.
- bag The table is a bag table which can have many objects, but only one instance of each object, per key.
- duplicate_bag The table is a duplicate bag table which can have many objects, including multiple copies of the same object, per key.
- public Any process may read or write to the table.
- protected The owner process can read and write to the table. Other processes can only read the table. This is the default setting for the access rights.
- private Only the owner process can read or write to the table.
- named_table If this option is present, the name Name is associated with the table identifier. The name can then be used instead of the table identifier in subsequent operations.
- {keypos,Pos} Specifies which element in the stored tuples should be used as key. By default, it is the first element, i.e. Pos=1. However, this is not always appropriate. In particular, we do not want the first element to be the key if we want to store Erlang records in a table.

Note that any tuple stored in the table must have at least Pos number of elements.

next(Tab, Key1) -> Key2 | '$end_of_table'

Types:
- **Tab** = tid() | atom()
- **Key1** = Key2 = term()

Returns the next key **Key2**, following the key **Key1** in the table **Tab**. If the table is of the ordered_set type, the next key in Erlang term order is returned. If the table is of any other type, the next key according to the table's internal order is returned. If there is no next key, "$end_of_table" is returned.

Use **first/1** to find the first key in the table.

Unless a table of type set, bag or duplicate_bag is protected using **safe_fixtable/2**, see below, a traversal may fail if concurrent updates are made to the table. If the table is of type ordered_set, the function returns the next key in order, even if the object does no longer exist.

```erlang
prev(Tab, Key1) ->
    Key2 = Key1,
    Key2 = Key2,
    Key2 = Key1,
    Key2 = Key2,
    Key2 = Key1,
    Key2 = Key2,
    Key2 = Key1,
    Key2 = Key2,
    Key2 = Key1,
    Key2 = Key2,
    Key2 = Key1,
    Key2 = Key2,
    Key2 = Key1,
    Key2 = Key2,
    Key2 = Key1,
    Key2 = Key2,
    Key2 = Key1,
    Key2 = Key2,
    Key2 = Key1,
    Key2 = Key2,
    Key2 = Key1,
    Key2 = Key2,
    Key2 = Key1,
    Key2 = Key2,
    Key2 = Key1,
    Key2 = Key2,
    Key2 = Key1,
    Key2 = Key2,
    Key2 = Key1,
    Key2 = Key2,
    Key2 = Key1,
    Key2 = Key2,
    Key2 = Key1,
    Key2 = Key2,
    Key2 = Key1,
    Key2 = Key2,
    Key2 = Key1,
    Key2 = Key2,
    Key2 = Key1,
    Key2 = Key2,
    Key2 = Key1,
    Key2 = Key2,
    Key2 = Key1,
    Key2 = Key2,
    Key2 = Key1,
    Key2 = Key2,
    Key2 = Key1,
    Key2 = Key2,
    Key2 = Key1,
    Key2 = Key2,
    Key2 = Key1,
    Key2 = Key2,
    Key2 = Key1,
    Key2 = Key2,
    Key2 = Key1,
    Key2 = Key2,
    Key2 = Key1,
    Key2 = Key2,
    Key2 = Key1,
    Key2 = Key2,
    Key2 = Key1,
    Key2 = Key2,
    Key2 = Key1,
    Key2 = Key2,
    Key2 = Key1,
    Key2 = Key2,
    Key2 = Key1,
    Key2 = Key2,
    Key2 = Key1,
    Key2 = Key2,
    Key2 = Key1,
    Key2 = Key2,
    Key2 = Key1,
    Key2 = Key2,
    Key2 = Key1,
    Key2 = Key2,
    Key2 = Key1,
    Key2 = Key2,
    Key2 = Key1,
    Key2 = Key2,
    Key2 = Key1,
    Key2 = Key2,
    Key2 = Key1,
    Key2 = Key2,
    Key2 = Key1,
    Key2 = Key2,
    Key2 = Key1,
    Key2 = Key2,
    Key2 = Key1,
    Key2 = Key2,
    Key2 = Key1,
    Key2 = Key2,
    Key2 = Key1,
    Key2 = Key2,
    Key2 = Key1,
    Key2 = Key2,
    Key2 = Key1,

clean_all_with_value(Tab, X) ->
  safe_fixtable(Tab, true),
  clean_all_with_value(Tab, X, ets:first(Tab)),
  safe_fixtable(Tab, false).

clean_all_with_value(Tab, X, '$end.of.table') ->
  true;
clean_all_with_value(Tab, X, Key) ->
  case ets:lookup(Tab, Key) of
    [{Key, X}] ->
      ets:delete(Tab, Key);
    _ ->
      true
  end,
  clean_all_with_value(Tab, X, ets:next(Tab, Key)).

Note that no deleted objects are actually removed from a fixed table until it has been released. If a process fixes a table but never releases it, the memory used by the deleted objects will never be freed. The performance of operations on the table will also degrade significantly.

Use info/2 to retrieve information about which processes have fixed which tables. A system with a lot of processes fixing tables may need a monitor which sends alarms when tables have been fixed for too long.

Note that for tables of the ordered set type, safe_fixtable/2 is not necessary as calls to first/1 and next/2 will always succeed.

select(Tab, MatchSpec) -> [Object]

Types:
- Tab = tid() | atom()
- Object = tuple()
- MatchSpec = term()

Matches the objects in the table Tab using a match spec as described in ERTS users guide. This is a more general call than the ets:match/2 and ets:match_object/2 calls. In its simplest forms the match spec’s look like this:

- MatchSpec = [MatchFunction]
- MatchFunction = {MatchHead, [Guard], [Result]}
- MatchHead = “Pattern as in ets:match”
- Guard = “Guardtest name”, ...
- Result = “Term construct”

This means that the match spec is always a list of one or more tuples (of arity 3). The tuples first element should be a pattern as described in the documentation of ets:match/2. The second element of the tuple should be a list of 0 or more guard tests (described below). The third element of the tuple should be a list containing a description of the value to actually return. In almost all normal cases the list contains exactly one term which fully describes the value to return for each object.

The return value is constructed using the “match variables” bound in the MatchHead or using the special match variables ‘$_’ (the whole matching object) and ‘$$’
match variables in a list), so that the following expression:

```erlang
ets:match(Tab,{'$1','$2','$3'})
```

is exactly equivalent to:

```erlang
ets:select(Tab,[[{'$1','$2','$3'},[],['$$']]])
```

- and the following call:

```erlang
ets:match_object(Tab,{'$1','$2','$1'})
```

is exactly equivalent to

```erlang
ets:select(Tab,[[{'$1','$2','$1'},[],['$_']]])
```

Composite terms can be constructed in the Result part either by simply writing a list, so that this code:

```erlang
ets:select(Tab,[[{'$1','$2','$3'},[],['$$']]])
```

gives the same output as:

```erlang
ets:select(Tab,[[{'$1','$2','$3'},[],['$$']]])
```

i.e. all the bound variables in the match head as a list. If tuples are to be constructed, one has to write a tuple of arity 1 with the single element in the tuple being the tuple one wants to construct (as an ordinary tuple could be mistaken for a guard). Therefore the following call:

```erlang
ets:select(Tab,[[{'$1','$2','$1'},[],['$_']]])
```

gives the same output as:

```erlang
ets:select(Tab,[[{'$1','$2','$1'},[],['$_']]])
```

- this syntax is equivalent to the syntax used in the trace patterns (see the `dbg` module in the `runtime_tools` application).

The guard’s are constructed as tuples where the first element is the name of the test (again, see the `match_spec` documentation in ERTS user guide) and the rest of the elements are the parameters of the test. To check for a specific type (say a list) of the element bound to the match variable `$1', one would write the test as `is_list, '$_'). If the test fails, the object in the table won’t match and the next `MatchFunction' (if any) will be tried. Most guard tests present in Erlang can be used, but only the new versions prefixed is, are allowed (like `is_float, is_atom' etc). An exact list of the allowed guard tests is present in the `match_spec' section of ERTS user guide.

The guard section can also contain logic and arithmetic operations, which are written with the same syntax as the guard tests (prefix notation), so that a guard test written in Erlang looking like this:

```erlang
is_integer(X), is_integer(Y), X + Y < 4711
```

is expressed like this (X replaced with `$1' and Y with `$2'):

```erlang
[[is_integer, '$1'], [is_integer, '$2'], {'<', {'+', '$1', '$2'}, 4711]]
```

A complete list of the operators is present in the `match_spec' section of ERTS user guide.

```erlang
select(Tab, MatchSpec, Limit) -> [Match],Continuation] | '$end_of_table'
```
Types:
- Tab = tid() | atom()
- Object = tuple()
- MatchSpec = term()
- Continuation = term()

Works like ets:select/2 but only returns a limited (Limit) number of matching objects. The Continuation term can then be used in subsequent calls to ets:select/1 to get the next chunk of matching objects. This is a space efficient way to work on objects in a table which is still faster than traversing the table object by object using ets:first/1 and ets:next/1.

'$end_of_table' is returned if the table is empty.

select(Continuation) -> { [Match], Continuation } | '$end_of_table'

Types:
- Match = [term()]
- Continuation = term()

Continues a match started with ets:select/3. The next chunk of the size given in the initial ets:select/3 call is returned together with a new Continuation that can be used in subsequent calls to this function.

'$end_of_table' is returned when there are no more objects in the table.

select_delete(Tab, MatchSpec) -> NumDeleted

Types:
- Tab = tid() | atom()
- Object = tuple()
- MatchSpec = term()
- NumDeleted = integer()

Matches the objects in the table Tab using a match_spec as described in ERTS users guide. If the match_spec returns the atom true for an object, that object is removed from the table. For any other result from the match_spec the object is retained. This is a more general call than the ets:match_delete/2 call.

The function returns the number of objects actually deleted from the table.

select_count(Tab, MatchSpec) -> NumMatched

Types:
- Tab = tid() | atom()
- Object = tuple()
- MatchSpec = term()
- NumMatched = integer()
Matches the objects in the table `Tab` using a match_spec as described in ERTS users guide. If the match_spec returns the atom `true` for an object, that object considered a match and is counted. For any other result from the match_spec the object is not considered a match and is therefore not counted.

The function could be described as a match_delete/2 that does not actually delete any elements, but only counts them.

The function returns the number of objects matched.

\[
\text{slot(Tab, I) -> [Object] | 'end of table'}
\]

Types:
- `Tab` = tid() | atom()
- `I` = int()
- `Object` = tuple()

**Warning:**
The function is deprecated and may be removed from future releases. Use first/next or last/prev instead.

Returns all objects in the I:th slot of the table `Tab`. A table can be traversed by repeatedly calling the function, starting with the first slot `I=0` and ending when `'$end of table'` is returned. The function will fail with reason `badarg` if the `I` argument is out of range.

Unless a table of type `set`, `bag` or `duplicate_bag` is protected using `safe_fixtable/2`, see above, a traversal may fail if concurrent updates are made to the table. If the table is of type `ordered_set`, the function returns a list containing the I:th object in Erlang term order.

\[
\text{tab2file(Tab, Filename) -> ok | {error,Reason}}
\]

Types:
- `Tab` = tid() | atom()
- `Filename` = string() | atom()
- `Reason` = term()

Dumps the table `Tab` to the file `Filename`. The implementation of this function is not efficient.

\[
\text{tab2list(Tab) -> [Object]}
\]

Types:
- `Tab` = tid() | atom()
- `Object` = tuple()

Returns a list of all objects in the table `Tab`.

\[
\text{test_ms(Tuple, MatchSpec) -> {ok, Result} | {error, Errors}}
\]

Types:
- `Tuple` = tuple()
- MatchSpec = term()
- Result = term()
- Errors = [{warning|error, string()}]

This function is a utility to test the match spec's used in calls to ets:select/2. The function both tests the MatchSpec for "syntactic" correctness and runs the match spec against the object Tuple. If the match spec contains errors, the tuple {error, Errors} is returned where Errors is a list of natural language descriptions of what was wrong with the match spec. If the match spec is syntactically OK, the function returns {ok,Term} where Term is what would have been the result in a real ets:select/2 call or false if the match spec does not match the object Tuple.

This is a useful debugging and test tool, especially when writing complicated ets:select/2 calls.

to_dets(Tab, DetsTab) -> Tab

Types:
- Tab = tid() | atom()
- DetsTab = atom()

Fills an already created/opened DETS table with the objects in the already opened ETS table named Tab. The DETS table is emptied before the objects are inserted.

update_counter(Tab, Key, {Pos,Incr}) -> Result
update_counter(Tab, Key, Incr) -> Result

Types:
- Tab = tid() | atom()
- Key = term()
- Pos = Incr = Result = int()

This functions provides an efficient way to update a counter, without the hassle of having to look up an object, update the object by incrementing an element and insert the resulting object into the table again.

It will destructively update the object with key Key in the table Tab by adding Incr to the element at the Pos:th position. The new counter value is returned. If no position is specified, the element directly following the key (<keypos>+1) is updated.

The function will fail with reason badarg if:

- the table is not of type set or ordered_set,
- no object with the right key exists,
- the object has the wrong arity, or,
- the element to update is not an integer.
The functions of this module sort terms on files, merge already sorted files, and check files for sortedness. Chunks containing binary terms are read from a sequence of files, sorted internally in memory and written on temporary files, which are merged producing one sorted file as output. Merging is provided as an optimization; it is faster when the files are already sorted, but it always works to sort instead of merge.

On a file, a term is represented by a header and a binary. Two options define the format of terms on files:

- \{header, HeaderLength\}. HeaderLength determines the number of bytes preceding each binary and containing the length of the binary in bytes. Default is 4. The order of the header bytes is defined as follows: if \( B \) is a binary containing a header only, the size \( Size \) of the binary is calculated as \( <<\text{Size:HeaderLength/unit:8}} = B \).

- \{format, Format\}. The format determines the function that is applied to binaries in order to create the terms that will be sorted. The default value is \texttt{binary_term}, which is equivalent to \texttt{fun \{binary, to_term/1}. The value \texttt{binary} is equivalent to \texttt{fun(X) - X end}, which means that the binaries will be sorted as they are. This is the fastest format. If \texttt{Format} is \texttt{term}, \texttt{io:read/2} is called to read terms. In that case only the default value of the header option is allowed. The \texttt{format} option also determines what is written to the sorted output file: if \texttt{Format} is \texttt{term} then \texttt{io:format/3} is called to write each term, otherwise the binary prefixed by a header is written. Note that the binary written is the same binary that was read; the results of applying the \texttt{Format} function are thrown away as soon as the terms have been sorted. Reading and writing terms using the \texttt{io} module is very much slower than reading and writing binaries.

Other options are:

- \{order, Order\}. The default is to sort terms in ascending order, but that can be changed by the value \texttt{descending} or by giving an ordering function \texttt{Fun}. \texttt{Fun(A, B)} should return \texttt{true} if \( A \) comes before \( B \) in the ordering, \texttt{false} otherwise. Using an ordering function will slow down the sort considerably. The \texttt{keysort}, \texttt{keymerge} and \texttt{keycheck} functions do not accept ordering functions.

- \{unique, bool()\}. When sorting or merging files, only the first of a sequence of terms that compare equal is output if this option is set to \texttt{true}. The default value is \texttt{false} which implies that all terms that compare equal are output. When checking files for sortedness, a check that no pair of consecutive terms compares equal is done if this option is set to \texttt{true}. 
- \{tmpdir, TempDirectory\}. The directory where temporary files are put can be chosen explicitly. The default, implied by the value "", is to put temporary files on the same directory as the sorted output file. If output is a function (see below), the directory returned by file:get_cwd() is used instead. The names of temporary files are derived from the pid doing the sort; a typical name would be file_sorter_0_28_0.17, where 17 is a sequence number. Existing files will be overwritten. Temporary files are deleted unless some uncaught EXIT signal occurs.

- \{compressed, bool\}. Temporary files and the output file may be compressed. The default value false implies that written files are not compressed. Regardless of the value of the compressed option, compressed files can always be read. Note that reading and writing compressed files is significantly slower than reading and writing uncompressed files.

- \{size, Size\}. By default approximately 512*1024 bytes read from files are sorted internally. This option should rarely be needed.

- \{no_files, NoFiles\}. By default 16 files are merged at a time. This option should rarely be needed.

To summarize, here is the syntax of the options:

- Options = [Option] | Option
- Option = \{header, HeaderLength\} | \{format, Format\} | \{order, Order\} | \{unique, bool\} | \{tmpdir, TempDirectory\} | \{compressed, bool\} | \{size, Size\} | \{no_files, NoFiles\}
- HeaderLength = int() > 0
- Format = binary_term | term | binary | FormatFun
- FormatFun = fun(Binary) -> Term
- Order = ascending | descending | OrderFun
- OrderFun = fun(Term, Term) -> bool()
- TempDirectory = "" | file_name()
- Size = int() > 0
- NoFiles = int() > 1

As an alternative to sorting files, a function of one argument can be given as input. When called with the argument read the function is assumed to return end_of_input or \{end_of_input, Value\} when there is no more input (Value is explained below), or \{Objects, Fun\}, where Objects is a list of binaries or terms depending on the format and Fun is a new input function. Any other value is immediately returned as value of the current call to sort or keysort. Each input function will be called exactly once, and should an error occur, the last function is called with the argument close, the reply of which is ignored.

A function of one argument can be given as output. The results of sorting or merging the input is collected in a non-empty sequence of variable length lists of binaries or terms depending on the format. The output function is called with one list at a time, and is assumed to return a new output function. Any other return value is immediately returned as value of the current call to sort or keysort. Each output function is called exactly once. When some output function has been applied to all of the results or an error occurs, the last function is called with the argument close, and the reply is returned as value of the current call to sort or keysort. If a function is given as input and the last input function returns \{end_of_input, Value\}, the function given
as output will be called with the argument \{value, Value\}. This makes it easy to initiate the sequence of output functions with a value calculated by the input functions.

As an example, consider sorting the terms on a disk log file. A function that reads chunks from the disk log and returns a list of binaries is used as input. The results are collected in a list of terms.

```
sort(Log) ->
    \{ok, _\} = disk_log:open([\{name, Log\}, \{mode, read\only\}]),
    Input = input(Log, start),
    Output = output([],)
    Reply = file_sorter:sort(Input, Output, \{format, term\}),
    ok = disk_log:close(Log),
    Reply.
```

```
input(Log, Cont) ->
    fun(close) ->
        ok;
    (read) ->
        case disk_log:chunk(Log, Cont) of
            \{error, Reason\} ->
                \{error, Reason\};
            \{Cont2, Terms\} ->
                \{Terms, input(Log, Cont2)\};
            \{Cont2, Terms, _Badbytes\} ->
                \{Terms, input(Log, Cont2)\};
            eof ->
                end_of_input
        end,
    end.
```

```
output(L) ->
    fun(close) ->
        lists:append(lists:reverse(L));
    (Terms) ->
        output([Terms | L])
    end.
```

Further examples of functions as input and output can be found at the end of the file_sorter module; the term format is implemented with functions.

The possible values of \texttt{Reason} returned when an error occurs are:

- \texttt{bad_object,\{bad_object, FileName\}. Applying the format function failed for some binary, or the key(s) could not be extracted from some term.}
- \texttt{\{bad_term, FileName\}. \texttt{io:read/2} failed to read some term.}
- \texttt{\{file_error, FileName, Reason2\}. See file(3) for an explanation of Reason2.}
- \texttt{\{premature_eof, FileName\}. End-of-file was encountered inside some binary term.}
- \texttt{\{not_a_directory, FileName\}. The file supplied with the \texttt{tmpdir} option is not a directory.}

Types
Binary = binary() 
FileName = file_name() 
FileNames = [FileName] 
ICommand = read | close 
IReply = end_of_input | {end_of_input, Value} | {
[Object], Infun} | InputReply 
Infun = fun(ICommand) -> IReply 
Input = FileNames | Infun 
InputReply = Term 
KeyPos = int() > 0 | [int()] > 0 
OCommand = {value, Value} | [Object] | close 
OReply = Outfun | OutputReply 
Object = Term | Binary 
Outfun = fun(OCommand) -> OReply 
Output = FileName | Outfun 
OutputReply = Term 
Term = term() 
Value = Term

Exports

sort(FileName) -> Reply 
sort(Input, Output) -> Reply 
sort(Input, Output, Options) -> Reply 

Types:
• Reply = ok | {error, Reason} | InputReply | OutputReply

Sorts terms on files.
sort(FileName) is equivalent to sort([FileName], FileName).
sort(Input, Output) is equivalent to sort(Input, Output, []).

keysort(KeyPos, FileName) -> Reply 
keysort(KeyPos, Input, Output) -> Reply 
keysort(KeyPos, Input, Output, Options) -> Reply 

Types:
• Reply = ok | {error, Reason} | InputReply | OutputReply

Sorts tuples on files. The sort is performed on the element(s) mentioned in KeyPos. If two tuples compare equal on one element, next element according to KeyPos is compared. The sort is stable.
keysort(N, FileName) is equivalent to keysort(N, [FileName], FileName).
keysort(N, Input, Output) is equivalent to keysort(N, Input, Output, []).

merge(FileNames, Output) -> Reply 
merge(FileNames, Output, Options) -> Reply 

Types:
• Reply = ok | {error, Reason} | OutputReply
Merges terms on files. Each input file is assumed to be sorted.

merge(FileNames, Output) is equivalent to merge(FileNames, Output, []).

keymerge(KeyPos, FileNames, Output) -> Reply
keymerge(KeyPos, FileNames, Output, Options) -> Reply

Types:
- Reply = ok | {error, Reason} | OutputReply

Merges tuples on files. Each input file is assumed to be sorted on key(s).

keymerge(KeyPos, FileNames, Output) is equivalent to keymerge(KeyPos, FileNames, Output, []).

check(FileName) -> Reply
check(FileNames, Options) -> Reply

Types:
- Reply = {ok, [Result]} | {error, Reason}
- Result = {FileName, TermPosition, Term}
- TermPosition = int() > 1

Checks files for sortedness. If a file is not sorted, the first out-of-order element is returned. The first term on a file has position 1.

check(FileName) is equivalent to check([FileName], []).

keycheck(KeyPos, FileName) -> CheckReply
keycheck(KeyPos, FileNames, Options) -> Reply

Types:
- Reply = {ok, [Result]} | {error, Reason}
- Result = {FileName, TermPosition, Term}
- TermPosition = int() > 1

Checks files for sortedness. If a file is not sorted, the first out-of-order element is returned. The first term on a file has position 1.

keycheck(KeyPos, FileName) is equivalent to keycheck(KeyPos, [FileName], []).
The module `filename` provides a number of useful functions for analyzing and manipulating file names. These functions are designed so that the Erlang code can work on many different platforms with different formats for file names. With file name is meant all strings that can be used to denote a file. They can be short relative names like `foo.erl`, very long absolute names which include a drive designator and directory names like `D:\usr\local\bin\erl\lib\tools\foo.erl`, or any variations in between.

In Windows, all functions return file names with forward slashes only, even if the arguments contain backslashes. Use the `join/1` function to normalize a file name by removing redundant directory separators.

Exports

`absname(Filename) -> Absname`

Types:
- `Filename = string() | [string()] | atom()`
- `Absname = string()`

Converts a relative filename and returns an absolute name. No attempt is made to create the shortest absolute name, because this can give incorrect results on file systems which allow links.

Examples include:
- Assume (for UNIX) current directory `/usr/local`
- Assume (for WIN32) current directory `D:/usr/local`

  (for UNIX): `absname("foo")` -> `/usr/local/foo`
  (for WIN32): `absname("foo")` -> `D:/usr/local/foo`
  (for UNIX): `absname("../x")` -> `"/usr/local/..\x"`
  (for WIN32): `absname("../x")` -> `"D:/usr/local/..\x"`
  (for UNIX): `absname("/\")` -> `"/"`
  (for WIN32): `absname("/\")` -> `"D:/"`

`absname(Filename, Directory) -> Absname`

Types:
- `Filename = string() | [string()] | atom()`
- `Directory = string()`
- `Absname = string()`
This function works like absname/1, except that the directory to which the file name should be made relative is given explicitly in the Directory argument.

**basename(Filename)**

Types:
- Filename = string() | [string()] | atom()

Returns the part of the Filename after the last directory separator, or the Filename itself if it has no separators.

Examples include:
- basename("foo") -> "foo"
- basename("/usr/foo") -> "foo"
- basename("/") -> []

**basename(Filename, Ext) -> string()**

Types:
- Filename = Ext = string() | [string()] | atom()

Returns the last component of Filename with the extension Ext stripped. Use this function if you want to remove an extension which might, or might not, be there. Use rootname(basename(Filename)) if you want to remove an extension that exists, but you are not sure which one it is.

Examples include:
- basename("~/src/kalle.erl", ".erl") -> "kalle"
- basename("~/src/kalle.beam", ".erl") -> "kalle.beam"
- basename("~/src/kalle.old.erl", ".erl") -> "kalle.old"
- rootname(basename("~/src/kalle.erl")) -> "kalle"
- rootname(basename("~/src/kalle.beam")) -> "kalle"

**dirname(Filename) -> string()**

Types:
- Filename = string() | [string()] | atom()

Returns the directory part of Filename.

Examples include:
- dirname("/usr/src/kalle.erl") -> "/usr/src"
- dirname("kalle.erl") -> "."
- On Win32: filename:dirname("\usr\src\kalle.erl") -> "/usr/src"

**extension(Filename) -> string() | []**

Types:
- Filename = string() | [string()] | atom()

Given a file name string Filename, this function returns the file extension including the period. Returns an empty list if there is no extension.

Examples include:
extension("foo.erl") -> ".erl"
extension("beam.src/kalle") -> []

join(Components) -> string()

Types:
• Components = [string()]

Joins a list of file name Components with directory separators. If one of the elements in the Components list includes an absolute path, for example "/xxx", the preceding elements, if any, are removed from the result.
The result of the join function is "normalized":
  • There are no redundant directory separators.
  • In Windows, all directory separators are forward slashes and the drive letter is in lower case.

Examples include:
join("/usr/local", "bin") -> "/usr/local/bin"
join(["/usr", "local", "bin"] ) -> "/usr/local/bin"
join(["a/b///c/"]) -> "a/b/c"
join(["B:a\b///c/"]) -> "b:a/b/c" % On Windows only

join(Name1, Name2) -> string()

Types:
• Name1 = Name2 = string()

Joins two file name components with directory separators. Equivalent to
join([[Name1,Name2]]).

nativename(Path) -> string()

Types:
• Path = string()

Converts a filename in Path to a form accepted by the command shell and native applications on the current platform. On Windows, forward slashes will be converted to backward slashes. On all platforms, the name will be normalized as done by join/1.
Example:
(on UNIX) filename:nativename("/usr/local/bin/") -> "/usr/local/bin"
(on Win32) filename:nativename("/usr/local/bin") -> "\usr\local\bin"

pathtype(Path) -> absolute | relative | volumerelative

Returns one of absolute, relative, or volumerelative.

absolute The path name refers to a specific file on a specific volume.
Examples include:
relative The path name is relative to the current working directory on the current volume.
Example:

foo/bar, ../src

volumerelative The path name is relative to the current working directory on a specified volume, or it is a specific file on the current working volume.
Examples include:

In Windows
D:bar.erl, /bar/foo.erl
/temp

rootname(Filename) -> string()
rootname(Filename, Ext) -> string()

Types:
- Filename = Ext = string() o [string()] o atom()

rootname/1 returns all characters in Filename, except the extension.
rootname/2 works as rootname/1, except that the extension is removed only if it is Ext.
Examples include:

rootname("/beam.src/kalle") -> "/beam.src/kalle"
rootname("/beam.src/foo.erl") -> "/beam.src/foo"
rootname("/beam.src/foo.erl",".erl") -> "/beam.src/foo"
rootname("/beam.src/foo.beam",".erl") -> "/beam.src/foo.beam"

split(Filename) -> Components

Types:
- Filename = string() o [string()] o atom()
- Components = [string()]

Returns a list whose elements are the path components of Filename.
Examples include:

split("/usr/local/bin") -> ["/", "usr", "local", "bin"]
split("foo/bar") -> ["foo", "bar"]
split("a:\msdev\include") -> ["a:/", "msdev", "include"]

find_src(Module) -> {SourceFile, Options}
find_src(Module, Rules) -> {SourceFile, Options}

Types:
- Module = atom() o string()
- SourceFile = string()
- Options = [CompilerOption]
- CompilerOption = \{i, string()\} | \{outdir, string()\} | \{d, atom()\}

Finds the source file name and compilation options for a compiled module. The result can be fed to compile:file/2 in order to compile the file again.

The Module argument, which can be a string or an atom, specifies either the module name or the path to the source code, with or without the " .erl " extension. In either case, the module must be known by the code manager, i.e. code:which/1 must succeed.

Rules describe how the source directory is found, when the object code directory is known. Each rule is of the form \{BinSuffix, SourceSuffix\} and is interpreted as follows: If the end of the directory name where the object is located matches BinSuffix, then the suffix of the directory name is replaced by SourceSuffix. If the source file is found in the resulting directory, then the function returns that location together with Options. Otherwise, the next rule is tried, and so on.

The function returns \{SourceFile, Options\}. SourceFile is the absolute path to the source file without the " .erl " extension. Options include the options which are necessary to compile the file with compile:file/2, but excludes options such as report or verbose which do not change the way code is generated. The paths in the \{outdir, Path\} and \{i, Path\} options are guaranteed to be absolute.
**gb_sets**

Erlang Module

An implementation of ordered sets using Prof. Arne Andersson’s General Balanced Trees. This can be much more efficient than using ordered lists, for larger sets, but depends on the application. See notes below for details.

**Complexity note**

The complexity on set operations is bounded by either $O(|S|)$ or $O(|T| \cdot \log(|S|))$, where $S$ is the largest given set, depending on which is fastest for any particular function call. For operating on sets of almost equal size, this implementation is about 3 times slower than using ordered-list sets directly. For sets of very different sizes, however, this solution can be arbitrarily much faster; in practical cases, often between 10 and 100 times. This implementation is particularly suited for accumulating elements a few at a time, building up a large set (more than 100-200 elements), and repeatedly testing for membership in the current set.

As with normal tree structures, lookup (membership testing), insertion and deletion have logarithmic complexity.

**Exports**

- **empty()**
  Returns new, empty set.
  Alias: new(), for compatibility with ‘sets’.

- **is_empty(S)**
  Returns ‘true’ if $S$ is an empty set, and ‘false’ otherwise.

- **size(S)**
  Returns the number of nodes in the set as an integer. Returns 0 (zero) if the set is empty.

- **singleton(X)**
  Returns a set containing only the element $X$.

- **is_member(X, S)**
Returns ‘true’ if element X is a member of set S, and ‘false’ otherwise.
Alias: is_element(), for compatibility with ‘sets’.

\( \text{insert}(X, S) \)
Inserts element X into set S, returns the new set. Assumes that the element is not present in S.

\( \text{add}(X, S) \)
Adds element X to set S, returns the new set. If X is already an element in S, nothing is changed.
Alias: add_element(), for compatibility with ‘sets’.

\( \text{delete}(X, S) \)
Removes element X from set S, returns new set. Assumes that the element exists in the set.
Alias: del_element(), for compatibility with ‘sets’.

\( \text{delete\_any}(X, T) \)
Removes key X from set S if the key is present in the set, otherwise does nothing; returns new set.

\( \text{balance}(S) \)
Rebalances the tree representation of S. Note that this is rarely necessary, but may be motivated when a large number of elements have been deleted from the tree without further insertions. Rebalancing could then be forced in order to minimise lookup times, since deletion only does not rebalance the tree.

\( \text{union}(S_1, S_2) \)
Returns a new set that contains each element that is in either S1 or S2 or both, and no other elements.

\( \text{union}(Ss) \)
Returns a new set that contains each element that is in at least one of the sets in the list Ss, and no other elements.

\( \text{intersection}(S_1, S_2) \)
Returns a new set that contains each element that is in both S1 and S2, and no other elements.

\( \text{intersection}(Ss) \)
Returns a new set that contains each element that is in all of the sets in the list Ss, and no other elements.

\( \text{difference}(S_1, S_2) \)
Returns a new set that contains each element in S1 that is not also in S2, and no other elements.

Alias: subtract(), for compatibility with 'sets'.

\texttt{is\_subset(S1, S2)}

Returns 'true' if each element in S1 is also a member of S2, and 'false' otherwise.

\texttt{to\_list(S)}

Returns an ordered list of all elements in set S. The list never contains duplicates (of course).

\texttt{from\_list(List)}

Creates a set containing all elements in List, where List may be unordered and contain duplicates.

\texttt{from\_ordset(L)}

Turns an ordered-set list L into a set. The list must not contain duplicates.

\texttt{take\_smallest(S)}

Returns \{X, S1\}, where X is the smallest element in set S, and S1 is the set S with element X deleted. Assumes that the set S is nonempty.

\texttt{iterator(S)}

Returns an iterator that can be used for traversing the entries of set S; see 'next'. The implementation of this is very efficient; traversing the whole set using 'next' is only slightly slower than getting the list of all elements using 'to\_list' and traversing that. The main advantage of the iterator approach is that it does not require the complete list of all elements to be built in memory at one time.

\texttt{next(T)}

Returns \{X, T1\} where X is the smallest element referred to by the iterator T, and T1 is the new iterator to be used for traversing the remaining elements, or the atom 'none' if no elements remain.

\texttt{filter(P, S)}

Filters set S using predicate function P. Included for compatibility with 'sets'.

\texttt{fold(F, A, S)}

Folds function F over set S with A as the initial accumulator. Included for compatibility with 'sets'.

\texttt{is\_set(S)}

Returns 'true' if S appears to be a set, and 'false' otherwise. Not recommended; included for compatibility with 'sets'.
SEE ALSO

gb_trees(3) [page 136], ordsets(3) [page 194], sets(3) [page 215]
gb_trees

Erlang Module

An efficient implementation of Prof. Arne Andersson’s General Balanced Trees. These have no storage overhead compared to unbalanced binary trees, and their performance is in general better than AVL trees.

Data structure

Data structure:
- \{Size, Tree\}, where ‘Tree’ is composed of nodes of the form:
  - \{Key, Value, Smaller, Bigger\}, and the "empty tree" node:
  - nil.

There is no attempt to balance trees after deletions. Since deletions don’t increase the height of a tree, this should be O K.

Original balance condition \( h(T) \leq \text{ceil}(c \times \log(|T|)) \) has been changed to the similar (but not quite equivalent) condition \( 2^{-h(T)} \leq |T| - c \). This should also be O K.

Performance is comparable to the AVL trees in the Erlang book (and faster in general due to less overhead); the difference is that deletion works for these trees, but not for the book’s trees. Behaviour is logarithmic (as it should be).

Exports

empty()

Returns a new, empty tree.

is_empty(T)

Returns ‘true’ if T is an empty tree, and ‘false’ otherwise.

size(T)

Returns the number of nodes in the tree as an integer. Returns 0 (zero) if the tree is empty.

lookup(X, T)

Looks up key X in tree T; returns \{value, V\}, or ‘none’ if the key is not present.

get(X, T)
Retrieves the value stored with key X in tree T. Assumes that the key is present in the tree, crashes otherwise.

\texttt{insert(X, V, T)}

Inserts key X with value V into tree T; returns the new tree. Assumes that the key is not present in the tree, crashes otherwise.

\texttt{update(X, V, T)}

Updates key X to value V in tree T; returns the new tree. Assumes that the key is present in the tree.

\texttt{enter(X, V, T)}

Inserts key X with value V into tree T if the key is not present in the tree, otherwise updates key X to value V in T. Returns the new tree.

\texttt{delete(X, T)}

Removes key X from tree T; returns new tree. Assumes that the key is present in the tree, crashes otherwise.

\texttt{delete\_any(X, T)}

Removes key X from tree T if the key is present in the tree, otherwise does nothing; returns new tree.

\texttt{balance(T)}

Rebalances tree T. Note that this is rarely necessary, but may be motivated when a large number of entries have been deleted from the tree without further insertions. Rebalancing could then be forced in order to minimise lookup times, since deletion only does not rebalance the tree.

\texttt{is\_defined(X, T)}

Returns ‘true’ if key X is present in tree T, and ‘false’ otherwise.

\texttt{keys(T)}

Returns an ordered list of all keys in tree T.

\texttt{values(T)}

Returns the list of values for all keys in tree T, sorted by their corresponding keys. Duplicates are not removed.

\texttt{to\_list(T)}

Returns an ordered list of \{Key, Value\} pairs for all keys in tree T.

\texttt{from\_orddict(L)}
gb_trees

Turns an ordered list \( L \) of \( \{\text{Key, Value}\} \) pairs into a tree. The list must not contain duplicate keys.

**take_smallest(T)**

Returns \( \{X, V, T1\} \), where \( X \) is the smallest key in tree \( T \), \( V \) is the value associated with \( X \) in \( T \), and \( T1 \) is the tree \( T \) with key \( X \) deleted. Assumes that the tree \( T \) is nonempty.

**iterator(T)**

Returns an iterator that can be used for traversing the entries of tree \( T \); see ‘next’. The implementation of this is very efficient; traversing the whole tree using ‘next’ is only slightly slower than getting the list of all elements using ‘to_list’ and traversing that. The main advantage of the iterator approach is that it does not require the complete list of all elements to be built in memory at one time.

**next(S)**

Returns \( \{X, V, S1\} \) where \( X \) is the smallest key referred to by the iterator \( S \), and \( S1 \) is the new iterator to be used for traversing the remaining entries, or the atom ‘none’ if no entries remain.

**SEE ALSO**

gb_sets(3) [page 132], dict(3) [page 72],
A behaviour module for implementing event handling functionality. The OTP event handling model consists of a generic event manager process with an arbitrary number of event handlers which are added and deleted dynamically.

An event manager implemented using this module will have a standard set of interface functions and include functionality for tracing and error reporting. It will also fit into an OTP supervision tree. Refer to OTP Design Principles for more information.

Each event handler is implemented as a callback module exporting a pre-defined set of functions. The relationship between the behaviour functions and the callback functions can be illustrated as follows:

```
<table>
<thead>
<tr>
<th>gen_event module</th>
<th>Callback module</th>
</tr>
</thead>
<tbody>
<tr>
<td>-----------------</td>
<td>-----------------</td>
</tr>
<tr>
<td>gen_event:start</td>
<td>Module:init/1</td>
</tr>
<tr>
<td>gen_event:add_handler</td>
<td>Module:terminate/2</td>
</tr>
<tr>
<td>gen_event:add_suphandler</td>
<td>Module:terminate/2</td>
</tr>
<tr>
<td>gen_event:sync_notify</td>
<td>Module:terminate/2</td>
</tr>
<tr>
<td>gen_event:call</td>
<td>Module:terminate/2</td>
</tr>
<tr>
<td>-</td>
<td>Module:terminate/2</td>
</tr>
<tr>
<td>gen_event:delete_handler</td>
<td>Module:terminate/2</td>
</tr>
<tr>
<td>gen_event:swap_handler</td>
<td>Module:terminate/2</td>
</tr>
<tr>
<td>gen_event:swap_sup_handler</td>
<td>Module:terminate/2</td>
</tr>
<tr>
<td>gen_event:which_handlers</td>
<td>Module:terminate/2</td>
</tr>
<tr>
<td>gen_event:stop</td>
<td>Module:terminate/2</td>
</tr>
<tr>
<td>-</td>
<td>Module:terminate/2</td>
</tr>
</tbody>
</table>
```

Since each event handler is one callback module, an event manager will have several callback modules which are added and deleted dynamically. Therefore gen_event is more tolerant of callback module errors than the other behaviours. If a callback function for an installed event handler fails with `Reason`, or returns a bad value `Term`, the event manager will not fail. It will delete the event handler by calling the callback function.
Module:terminate/2 (see below), giving as argument \{error,\{'EXIT',Reason\}\} or \{error,Term\}, respectively. No other event handler will be affected.

The sys module can be used for debugging an event manager.

Note that an event manager does trap exit signals automatically.

Unless otherwise stated, all functions in this module fail if the specified event manager does not exist or if bad arguments are given.

Exports

\[\text{start() \rightarrow Result}\]
\[\text{start(EventMgrName) \rightarrow Result}\]
\[\text{start_link() \rightarrow Result}\]
\[\text{start_link(EventMgrName) \rightarrow Result}\]

Types:
- EventMgrName = \{local,Name\} | \{global,Name\}
- Name \(=\) atom()
- Result = \{ok,Pid\} | \{error,\{already_started,Pid\}\}
- Pid \(=\) pid()

Creates an event manager.

An event manager started using start_link is linked to the calling process. This function must be used if the event manager is included in a supervision tree. An event manager started using start is not linked to the calling process.

If EventMgrName=\{local,Name\}, the event manager is registered locally as Name using register/2. If EventMgrName=\{global,Name\}, the event manager is registered globally as Name using global:register_name/2. If no name is provided, the event manager is not registered.

If the event manager is successfully created the function returns \{ok,Pid\}, where Pid is the pid of the event manager. If there already exists a process with the specified EventMgrName the function returns \{error,\{already_started,Pid\}\}, where Pid is the pid of that process.

\[\text{add_handler(EventMgrRef, Handler, Args) \rightarrow Result}\]

Types:
- EventMgr = Name \| \{Name,Node\} \| \{global,Name\} \| pid()
- Name = Node = atom()
- Handler = Module \| \{Module,Id\}
- Module = atom()
- Id = term()
- Args = term()
- Result = ok \| \{'EXIT',Reason\} \| term()
- Reason = term()

 Adds a new event handler to the event manager EventMgrRef. The event manager will call Module:init/1 to initiate the event handler and its internal state.

EventMgrRef can be:
• the pid,
• Name, if the event manager is locally registered,
• \{Name, Node\}, if the event manager is locally registered at another node, or
• \{global, Name\}, if the event manager is globally registered.

Handler is the name of the callback module Module or a tuple \{Module, Id\}, where Id is any term. The \{Module, Id\} representation makes it possible to identify a specific event handler when there are several event handlers using the same callback module.

Args is an arbitrary term which is passed as the argument to Module:init/1.

If Module:init/1 returns a correct value, the event manager adds the event handler and this function returns \ok. If Module:init/1 fails with Reason or returns an unexpected value Term, the event handler is ignored and this function returns \{’EXIT’, Reason\} or Term, respectively.

add_sup_handler(EventMgrRef, Handler, Args) \rightarrow Result

Types:
• EventMgr = Name \| \{Name, Node\} \| \{global, Name\} \| pid()
• Name = Node = atom()
• Handler = Module \| \{Module, Id\}
• Module = atom()
• Id = term()
• Args = term()
• Result = \ok \| \{’EXIT’, Reason\} \| term()
• Reason = term()

Adds a new event handler in the same way as add_handler/3 but will also supervise the connection between the event handler and the calling process.

• If the calling process later terminates with Reason, the event manager will delete the event handler by calling Module:terminate/2 with \{stop, Reason\} as argument.
• If the event handler later is deleted, the event manager sends a message [gen_event EXIT, Handler, Reason] to the calling process. Reason is one of the following:
  - normal, if the event handler has been removed due to a call to delete_handler/3, or remove_handler has been returned by a callback function (see below).
  - shutdown, if the event handler has been removed because the event manager is terminating.
  - \{swapped, NewHandler, Pid\}, if the process Pid has replaced the event handler with another event handler NewHandler using a call to swap_handler/3 or swap_sup_handler/3.
  - a term, if the event handler is removed due to an error. Which term depends on the error.

See add_handler/3 for a description of the arguments and return values.

\notify(EventMgrRef, Event) \rightarrow \ok
\sync_notify(EventMgrRef, Event) \rightarrow \ok
**Types:**
- EventMgrRef = Name | {Name,Node} | {global,Name} | pid()
- Name = Node = atom()
- Event = term()

Sends an event notification to the event manager `EventMgrRef`. The event manager will call `Module:handle_event/2` for each installed event handler to handle the event.

`notify` is asynchronous and will return immediately after the event notification has been sent. `sync_notify` is synchronous in the sense that it will return `ok` after the event has been handled by all event handlers.

See `add_handler/3` for a description of `EventMgrRef`.

`Event` is an arbitrary term which is passed as one of the arguments to `Module:handle_event/2`.

`notify` will not fail even if the specified event manager does not exist, unless it is specified as `Name`.

```erlang
call(EventMgrRef, Handler, Request) -> Result
call(EventMgrRef, Handler, Request, Timeout) -> Result
```

**Types:**
- EventMgrRef = Name | {Name,Node} | {global,Name} | pid()
- Name = Node = atom()
- Handler = Module | {Module,Id}
- Module = atom()
- Id = term()
- Request = term()
- Timeout = int() > 0 | infinity
- Result = Reply | {error,Error}
- Reply = term()
- Error = bad_module | 'EXIT',Reason | term()
- Reason = term()

Makes a synchronous call to the event handler `Handler` installed in the event manager `EventMgrRef` by sending a request and waiting until a reply arrives or a timeout occurs. The event manager will call `Module:handle_call/2` to handle the request.

See `add_handler/3` for a description of `EventMgrRef` and `Handler`.

`Request` is an arbitrary term which is passed as one of the arguments to `Module:handle_call/2`.

`Timeout` is an integer greater than zero which specifies how many milliseconds to wait for a reply, or the atom `infinity` to wait indefinitely. Default value is 5000. If no reply is received within the specified time, the function call fails.

The return value `Reply` is defined in the return value of `Module:handle_call/2`. If the specified event handler is not installed, the function returns `{error,bad_module}`. If the callback function fails with `Reason` or returns an unexpected value `Term`, this function returns `{error,{'EXIT',Reason}}` or `{error,Term}`, respectively.

```erlang
delte_handler(EventMgrRef, Handler, Args) -> Result
```

**Types:**
• EventMgrRef = Name | {Name,Node} | {global,Name} | pid()
• Name = Node = atom()
• Handler = Module | {Module,Id}
• Module = atom()
• Id = term()
• Args = term()
• Result = term() | {error,module_not_found} | {'EXIT',Reason}
• Reason = term()

Deletes an event handler from the event manager EventMgrRef. The event manager will call Module:terminate/2 to terminate the event handler.

See add_handler/3 for a description of EventMgrRef and Handler.

Args is an arbitrary term which is passed as one of the arguments to Module:terminate/2.

The return value is the return value of Module:terminate/2. If the specified event handler is not installed, the function returns \{error,module_not_found\}. If the callback function fails with Reason, the function returns \{'EXIT',Reason\}.

\[\text{swap_handler}(\text{EventMgrRef}, \{\text{Handler1,Args1}\}, \{\text{Handler2,Args2}\}) \rightarrow \text{Result}\]

Types:
• EventMgrRef = Name | {Name,Node} | {global,Name} | pid()
• Name = Node = atom()
• Handler1 = Handler2 = Module | {Module,Id}
• Module = atom()
• Id = term()
• Args1 = Args2 = term()
• Result = ok | {error,Error}
• Error = {'EXIT',Reason} | term()
• Reason = term()

Replaces an old event handler with a new event handler in the event manager EventMgrRef.

See add_handler/3 for a description of the arguments.

First the old event handler Handler1 is deleted. The event manager calls Module1:terminate(Args1, ...), where Module1 is the callback module of Handler1, and collects the return value.

Then the new event handler Handler2 is added and initiated by calling Module2:init([Args2,Term]), where Module2 is the callback module of Handler2 and Term the return value of Module1:terminate/2. This makes it possible to transfer information from Handler1 to Handler2.

The new handler will be added even if the the specified old event handler is not installed in which case Term=error, or if Module1:terminate/2 fails with Reason in which case Term={'EXIT',Reason}. The old handler will be deleted even if Module2:init/1 fails.

If there was a supervised connection between Handler1 and a process Pid, there will be a supervised connection between Handler2 and Pid instead.

If Module2:init/1 returns a correct value, this function returns ok. If Module2:init/1 fails with Reason or returns an unexpected value Term, this this function returns \{error,{'EXIT',Reason}\} or \{error,Term\}, respectively.
swap_sup_handler(EventMgrRef, {Handler1,Args1}, {Handler2,Args2}) -> Result

Types:
- EventMgrRef = Name | {Name,Node} | {global,Name} | pid()
- Name = Node = atom()
- Handler1 = Handler2 = Module | {Module,Id}
- Module = atom()
- Id = term()
- Args1 = Args2 = term()
- Result = ok | {error,Error}
- Error = ['EXIT',Reason] | term()
- Reason = term()

Replaces an event handler in the event manager EventMgrRef in the same way as swap_handler/3 but will also supervise the connection between Handler2 and the calling process.

See swap_handler/3 for a description of the arguments and return values.

which_handlers(EventMgrRef) -> [Handler]

Types:
- EventMgrRef = Name | {Name,Node} | {global,Name} | pid()
- Name = Node = atom()
- Handler = Module | {Module,Id}
- Module = atom()
- Id = term()

Returns a list of all event handlers installed in the event manager EventMgrRef.

See add_handler/3 for a description of EventMgrRef and Handler.

stop(EventMgrRef) -> ok

Types:
- EventMgrRef = Name | {Name,Node} | {global,Name} | pid()
- Name = Node = atom()

Terminates the event manager EventMgrRef. Before terminating, the event manager will call Module:terminate(stop,...) for each installed event handler.

See add_handler/3 for a description of the argument.

CALLBACK FUNCTIONS

The following functions should be exported from a gen_event callback module.
Exports

Module:init(InitArgs) -> {ok, State}

Types:
- InitArgs = A rgs | {Args, Term}
- Args = Term = term()
- State = term()

Whenever a new event handler is added to an event manager, this function is called to initialize the event handler.

If the event handler is added due to a call to gen_event:add_handler/3 or gen_event:add_sup_handler/3, InitArgs is the Args argument of these functions.

If the event handler is replacing another event handler due to a call to gen_event:swap_handler/3 or gen_event:swap_sup_handler/3, or due to a swap return tuple from one of the other callback functions, InitArgs is a tuple {Args, Term} where Args is the argument provided in the function call/return tuple and Term is the result of terminating the old event handler, see gen_event:swap_handler/3.

The function should return {ok, State} where State is the initial internal state of the event handler.

Module:handle_event(Event, State) -> Result

Types:
- Event = term()
- State = term()
- Result = {ok, NewState}
- | {swap_handler, Args1, NewState, Handler2, Args2} | remove_handler
- NewState = term()
- Args1 = Args2 = term()
- Handler2 = Module2 | {Module2, Id}
- Module2 = atom()
- Id = term()

Whenever an event manager receives an event sent using gen_event:notify/2 or gen_event:sync_notify/2, this function is called for each installed event handler to handle the event.

Event is the Event argument of notify/sync_notify.
State is the internal state of the event handler.

If the function returns {ok, NewState} the event handler will remain in the event manager with the possible updated internal state NewState.

If the function returns {swap_handler, Args1, NewState, Handler2, Args2} the event handler will be replaced by Handler2 by first calling Module:terminate(Args1, NewState) and then Module2:init({Args2, Term}) where Term is the return value of Module:terminate/2. See gen_event:swap_handler/3 for more information.

If the function returns remove_handler the event handler will be deleted by calling Module:terminate(remove_handler, State).
Module:handle_call(Request, State) -> Result

Types:
- Request = term()
- State = term()
- Result = [ok, Reply, NewState]
- NewState = term()
- Handler2 = Module2 | {Module2, Id}
- Module2 = atom()
- Id = term()

Whenever an event manager receives a request sent using `gen_event:call/3,4`, this function is called for the specified event handler to handle the request.

Request is the Request argument of `call`.
State is the internal state of the event handler.
The return values are the same as for `handle_event/2` except they also contain a term Reply which is the reply given back to the client as the return value of `call`.

Module:handle_info(Info, State) -> Result

Types:
- Info = term()
- State = term()
- Result = [ok, NewState]
- NewState = term()
- Handler2 = Module2 | {Module2, Id}
- Module2 = atom()
- Id = term()

This function is called for each installed event handler when an event manager receives any other message than an event or a synchronous request (or a system message).

Info is the received message.
See Module:handle_event/2 for a description of State and possible return values.

Module:terminate(Arg, State) -> term()

Types:
- Arg = Args | {stop, Reason} | stop | remove_handler
- Args = Reason = Term = term()
Whenever an event handler is deleted from an event manager, this function is called. It should be the opposite of Module:init/1 and do any necessary cleaning up.

If the event handler is deleted due to a call to gen_event:delete_handler, gen_event:swap_handler/3 or gen_event:swap_sup_handler/3, Arg is the Args argument of this function call.

Arg=[stop, Reason] if the event handler has a supervised connection to a process which has terminated with reason Reason.

Arg=stop if the event handler is deleted because the event manager is terminating.

Arg=remove_handler if the event handler is deleted because another callback function has returned remove_handler or [remove_handler, Reply].

Arg=[error, Term] if the event handler is deleted because a callback function returned an unexpected value Term, or Arg=[error, {'EXIT', Reason}] if a callback function failed.

State is the internal state of the event handler.

The function may return any term. If the event handler is deleted due to a call to gen_event:delete_handler, the return value of that function will be the return value of this function. If the event handler is to be replaced with another event handler due to a swap, the return value will be passed to the init function of the new event handler. Otherwise the return value is ignored.

Module:code_change(OldVsn, State, Extra) -> {ok, NewState}

Types:
- OldVsn = undefined | term()
- State = NewState = term()
- Extra = term()

This function is called for each installed event handler they should update the internal state due to code replacement, i.e. when the instruction {update, Module, Change, PrePurge, PostPurge, Modules} where Change=advanced, Extra} has been given to the release handler. See SASL User's Guide for more information.

OldVsn is the vsn attribute of the old version of the callback module Module, or undefined if no such attribute is defined.

State is the internal state of the event handler.

Extra is the same as in the {advanced, Extra} part of the update instruction.

The function should return {ok, NewState}, where NewState is the updated internal state.

SEE ALSO

supervisor(3), sys(3)
A behaviour module for implementing a finite state machine. A generic finite state machine process (gen_fsm) implemented using this module will have a standard set of interface functions and include functionality for tracing and error reporting. It will also fit into an OTP supervision tree. Refer to OTP Design Principles for more information.

A gen_fsm assumes all specific parts to be located in a callback module exporting a pre-defined set of functions. The relationship between the behaviour functions and the callback functions can be illustrated as follows:

```
- gen_fsm module
  -------------------
  gen_fsm:start_link  -----> Module:init/1
  gen_fsm:send_event   -----> Module:StateName/2
  gen_fsm:send_all_state_event -----> Module:handle_event/3
  gen_fsm:sync_send_event    -----> Module:StateName/3
  gen_fsm:sync_send_all_state_event -----> Module:handle_sync_event/4
  -                                  -----> Module:handle_info/3
  -                                  -----> Module:terminate/3
  -                                  -----> Module:code_change/4
```

If a callback function fails or returns a bad value, the gen_fsm will terminate.

The sys module can be used for debugging a gen_fsm.

Note that a gen_fsm does not trap exit signals automatically, this must be explicitly initiated in the callback module.

Unless otherwise stated, all functions in this module fail if the specified gen_fsm does not exist or if bad arguments are given.
Exports

\[\text{start(Module, Args, Options)} \rightarrow \text{Result}\\
\text{start(FsmName, Module, Args, Options)} \rightarrow \text{Result}\\
\text{start_link(Module, Args, Options)} \rightarrow \text{Result}\\
\text{start_link(FsmName, Module, Args, Options)} \rightarrow \text{Result}\]

Types:
- \(\text{FsmName} = \{\text{local,Name}\} \mid \{\text{global,Name}\}\)
- \(\text{Name} = \text{atom}\()\)
- \(\text{Module} = \text{atom}\()\)
- \(\text{Args} = \text{term}\()\)
- \(\text{Options} = \{\text{Option}\}\)
- \(\text{Option} = \{\text{timeout,Time}\} \mid \{\text{spawn_opt,SOpts}\}\)
- \(\text{Dbgs} = \{\text{Dbg}\}\)
- \(\text{Dbg} = \text{trace} \mid \text{log} \mid \text{statistics} \mid \{\text{log_to_file,FileName}\} \mid \{\text{install,\{Func,FuncState\}\}\}
- \(\text{SOpts} = \{\text{term}\}\)
- \(\text{Result} = \{\text{ok,Pid}\} \mid \text{ignore} \mid \{\text{error,Error}\}\)
- \(\text{Pid} = \text{pid}\()\)
- \(\text{Error} = \{\text{already_started,Pid}\} \mid \text{term}\()\)

Creates a gen\_fsm process which calls Module:init/1 to initialize. To ensure a synchronized start-up procedure, this function does not return until Module:init/1 has returned.

A gen\_fsm started using start_link is linked to the calling process, this function must be used if the gen\_fsm is included in a supervision tree. A gen\_fsm started using start is not linked to the calling process.

If FsmName=\{local,Name\}, the gen\_fsm is registered locally as Name using register/2.
If FsmName=\{global,Name\}, the gen\_fsm is registered globally as Name using global:register_name/2. If no name is provided, the gen\_fsm is not registered.

Module is the name of the callback module.

Args is an arbitrary term which is passed as the argument to Module:init/1.

If the option \{timeout,Time\} is present, the gen\_fsm is allowed to spend Time milliseconds initializing or it will be terminated and the start function will return \{error,timeout\}.

If the option \{debug,Dbgs\} is present, the corresponding sys function will be called for each item in Dbgs. Refer to sys(3) for more information.

If the option \{spawn_opt,SOpts\} is present, SOpts will be passed as option list to the spawn_opt BIF which is used to spawn the gen\_fsm process. Refer to erlang(3) for information about the spawn_opt options.

If the gen\_fsm is successfully created and initialized the function returns \{ok,\text{Pid}\}, where \text{Pid} is the pid of the gen\_fsm. If there already exists a process with the specified FsmName, the function returns \{error,\{already_started,\text{Pid}\}\} where \text{Pid} is the pid of that process.

If Module:init/1 fails with Reason, the function returns \{error,Reason\}. If Module:init/1 returns \{stop,Reason\} or ignore, the process is terminated and the function returns \{error,Reason\} or ignore, respectively.
send_event(FsmRef, Event) -> ok

Types:
- FsmRef = Name | {Name,Node} | {global,Name} | pid()
- Name = Node = atom()
- Event = term()

Sends an event asynchronously to the gen_fsm FsmRef and returns ok immediately. The gen_fsm will call Module:StateName/2 to handle the event, where StateName is the name of the current state of the gen_fsm.

FsmRef can be:
- the pid,
- Name, if the gen_fsm is locally registered,
- {Name,Node}, if the gen_fsm is locally registered at another node, or
- {global,Name}, if the gen_fsm is globally registered.

Event is an arbitrary term which is passed as one of the arguments to Module:StateName/2.

call(FsmRef, Event) -> ok

call(FsmRef, Event, Timeout) -> ok

Types:
- FsmRef = Name | {Name,Node} | {global,Name} | pid()
- Name = Node = atom()
- Event = term()
- Timeout = int() >= 0 | infinity
- Reply = term()

Sends an event asynchronously to the gen_fsm FsmRef and returns ok immediately. The gen_fsm will call Module:handle_event/3 to handle the event.

See send_event/2 for a description of the arguments.

The difference between send_event and call is which callback function is used to handle the event. This function is useful when sending events that are handled the same way in every state, as only one handle_event clause is needed to handle the event instead of one clause in each state name function.

call(FsmRef, Event) -> Reply

call(FsmRef, Event, Timeout) -> Reply

Types:
- FsmRef = Name | {Name,Node} | {global,Name} | pid()
- Name = Node = atom()
- Event = term()
- Timeout = int() >= 0 | infinity
- Reply = term()
Sends an event to the gen_fsm FsmRef and waits until a reply arrives or a timeout occurs. The gen_fsm will call Module:StateName/3 to handle the event, where StateName is the name of the current state of the gen_fsm.

See `send_event/2` for a description of FsmRef and Event.

Timeout is an integer greater than zero which specifies how many milliseconds to wait for a reply, or the atom infinity to wait indefinitely. Default value is 5000. If no reply is received within the specified time, the function call fails.

The return value Reply is defined in the return value of Module:StateName/3.

In the case where the gen_fsm terminates during the handling of the event and the caller is linked to the gen_fsm and trapping exits, the exit message is removed from the caller’s receive queue before the function call fails.

This behaviour is retained for backwards compatibility only and may change in the future. Note that if the gen_fsm crashes in between calls, a linked process must take care of the exit message anyway.

Warning: Under certain circumstances (e.g. FsmRef = {Name,Node}, and Node goes down) the exit message cannot be removed.

```
sync_send_all_state_event(FsmRef, Event) -> Reply
sync_send_all_state_event(FsmRef, Event, Timeout) -> Reply
```

Types:
- FsmRef = Name | {Name,Node} | {global,Name} | pid()
- Name = Node = atom()
- Event = term()
- Timeout = int() > 0 | infinity
- Reply = term()

Sends an event to the gen_fsm FsmRef and waits until a reply arrives or a timeout occurs. The gen_fsm will call Module:handle_event/3 to handle the event.

See `send_event/2` for a description of FsmRef and Event. See `sync_send_event/3` for a description of Timeout and Reply.

See `send_all_state_event/2` for a discussion about the difference between `sync_send_event` and `sync_send_all_state_event`.

```
reply(Caller, Reply) -> true
```

Types:
- Caller - see below
- Reply = term()

This function can be used by a gen_fsm to explicitly send a reply to a client process that called `sync_send_event` or `sync_send_all_state_event`, when the reply cannot be defined in the return value of Module:State/3 or Module:handle_sync_event/4.

Caller must be the From argument provided to the callback function. Reply is an arbitrary term, which will be given back to the client as the return value of `sync_send_event` or `sync_send_all_state_event`.
CALLBACK FUNCTIONS

The following functions should be exported from a gen_fsm callback module. In the description, the expression state name is used to denote a state of the state machine. state data is used to denote the internal state of the Erlang process which implements the state machine.

Exports

Module:init(Args) -> Result

Types:
- Args = term()
- Return = [ok,StateName,StateData] | [ok,StateName,StateData,Timeout]
- | [stop,Reason] | ignore
- StateName = atom()
- StateData = term()
- Timeout = int() > 0 | infinity
- Reason = term()

Whenever a gen_fsm is started using gen_fsm:start/3,4 or gen_fsm:start_link/3,4, this function is called by the new process to initialize. Args is the Args argument provided to the start function.

If initialization is successful, the function should return [ok,StateName,StateData] or [ok,StateName,StateData,Timeout], where StateName is the initial state name and StateData the initial state data of the gen_fsm.

If an integer timeout value is provided, a timeout will occur unless an event or a message is received within Timeout milliseconds. A timeout is represented by the atom timeout and should be handled by the Module:StateName/2 callback functions. The atom infinity can be used to wait indefinitely, this is the default value.

If something goes wrong during the initialization the function should return [stop,Reason], where Reason is any term, or ignore.

Module:StateName(Event, StateData) -> Result

Types:
- Event = timeout | term()
- StateData = term()
- Result = [next_state,NextStateName,NewStateData] | [next_state,NextStateName,NewStateData,Timeout]
- | [stop,Reason,NewStateData]
- NextStateName = atom()
- NewStateData = term()
- Timeout = int() > 0 | infinity
- Reason = term()
There should be one instance of this function for each possible state name. Whenever a gen_fsm receives an event sent using gen_fsm:send_event/2, the instance of this function with the same name as the current state name StateName is called to handle the event. It is also called if a timeout occurs.

Event is either the atom timeout, if a timeout has occurred, or the Event argument provided to send_event.

StateData is the state data of the gen_fsm.

If the function returns \{next_state,NextStateName,NewStateData\} or \{next_state,NextStateName,NewStateData,Timeout\}, the gen_fsm will continue executing with the current state name set to NextStateName and with the possibly updated state data NewStateData. See Module:init/1 for a description of Timeout.

If the function returns \{stop,Reason,NewStateData\}, the gen_fsm will call Module:terminate(Reason,NewStateData) and terminate.

Module:handle_event(Event, StateName, StateData) -> Result

Types:
- Event = term()
- StateName = atom()
- StateData = term()
- Result = \{next_state,NextStateName,NewStateData\} | \{next_state,NextStateName,NewStateData,Timeout\}
- | \{stop,Reason,NewStateData\}
- NextStateName = atom()
- NewStateData = term()
- Timeout = int() > 0 | infinity
- Reason = term()

Whenever a gen_fsm receives an event sent using gen_fsm:send_all_state_event/2, this function is called to handle the event.

StateName is the current state name of the gen_fsm.

See Module:StateName/2 for a description of the other arguments and possible return values.

Module:StateName(Event, From, StateData) -> Result

Types:
- Event = term()
- From = \{pid(),Tag\}
- StateData = term()
- Result = \{reply,Reply,NextStateName,NewStateData\} | \{reply,Reply,NextStateName,NewStateData,Timeout\}
- | \{next_state,NextStateName,NewStateData\} | \{next_state,NextStateName,NewStateData,Timeout\}
- | \{stop,Reason,Reply,NewStateData\} | \{stop,Reason,NewStateData\}
- Reply = term()
- NextStateName = atom()
- NewStateData = term()
- Timeout = int() > 0 | infinity
There should be one instance of this function for each possible state name. Whenever a \texttt{gen\_fsm} receives an event sent using \texttt{gen\_fsm:sync\_send\_event/}2,3, the instance of this function with the same name as the current state name \texttt{StateName} is called to handle the event.

\texttt{Event} is the Event argument provided to \texttt{sync\_send\_event}. From is a tuple \{\texttt{Pid}, \texttt{Tag}\} where \texttt{Pid} is the pid of the process which called \texttt{sync\_send\_event} and \texttt{Tag} is a unique tag. \texttt{StateData} is the state data of the \texttt{gen\_fsm}.

If the function returns \{\texttt{reply}, \texttt{Reply}, \texttt{NextStateName}, \texttt{NewStateData}\} or \{\texttt{reply}, \texttt{Reply}, \texttt{NextStateName}, \texttt{NewStateData}, \texttt{Timeout}\}, \texttt{Reply} will be given back to \texttt{From} as the return value of \texttt{sync\_send\_event}. The \texttt{gen\_fsm} then continues executing with the current state name set to \texttt{NextStateName} and with the possibly updated state data \texttt{NewStateData}. See Module: \texttt{init/}1 for a description of \texttt{Timeout}.

If the function returns \{\texttt{next\_state}, \texttt{NextStateName}, \texttt{NewStateData}\} or \{\texttt{next\_state}, \texttt{NextStateName}, \texttt{NewStateData}, \texttt{Timeout}\}, the \texttt{gen\_fsm} will continue executing in \texttt{NextStateName} with \texttt{NewStateData}. Any reply to \texttt{From} must be given explicitly using \texttt{gen\_fsm:reply/}2.

If the function returns \{\texttt{stop}, \texttt{Reason}, \texttt{Reply}, \texttt{NewStateData}\}, \texttt{Reply} will be given back to \texttt{From}. If the function returns \{\texttt{stop}, \texttt{Reason}, \texttt{NewStateData}\}, any reply to \texttt{From} must be given explicitly using \texttt{gen\_fsm:reply/}2. The \texttt{gen\_fsm} will then call Module: \texttt{terminate(Reason,NewStateData) and terminate.}

\texttt{Module:handle\_sync\_event(Event, From, StateName, StateData) -> Result}

Types:

- \texttt{Event} = \texttt{term()}
- \texttt{From} = \{\texttt{pid()}, \texttt{Tag}\}
- \texttt{StateName} = \texttt{atom()}
- \texttt{StateData} = \texttt{term()}
- \texttt{Result} = \{\texttt{reply}, \texttt{Reply}, \texttt{NextStateName}, \texttt{NewStateData}\} | \{\texttt{reply}, \texttt{Reply}, \texttt{NextStateName}, \texttt{NewStateData}, \texttt{Timeout}\} | \{\texttt{next\_state}, \texttt{NextStateName}, \texttt{NewStateData}\} | \{\texttt{next\_state}, \texttt{NextStateName}, \texttt{NewStateData}, \texttt{Timeout}\} | \{\texttt{stop}, \texttt{Reason}, \texttt{Reply}, \texttt{NewStateData}\} | \{\texttt{stop}, \texttt{Reason}, \texttt{NewStateData}\}
- \texttt{Reply} = \texttt{term()}
- \texttt{NextStateName} = \texttt{atom()}
- \texttt{NewStateData} = \texttt{term()}
- \texttt{Timeout} = \texttt{int()} > 0 | \texttt{infinity}
- \texttt{Reason} = \texttt{term()}

Whenever a \texttt{gen\_fsm} receives an event sent using \texttt{gen\_fsm:sync\_send\_all\_state\_event/}2,3, this function is called to handle the event. StateName is the current state name of the \texttt{gen\_fsm}.

See Module: \texttt{StateName/3} for a description of the other arguments and possible return values.

\texttt{Module:handle\_info(Info, StateName, StateData) -> Result}
Types:
- \texttt{Info = term()}
- \texttt{StateName = atom()}
- \texttt{StateData = term()}
- \texttt{Result = \{next\_state,NextStateName,NewStateData\} |}
  \texttt{\{next\_state,NextStateName,NewStateData,Timeout\}}
- \texttt{\{stop,Reason,NewStateData\}}
- \texttt{NextStateName = atom()}
- \texttt{NewStateData = term()}
- \texttt{Timeout = int() > 0 | infinity}
- \texttt{Reason = normal | term()}

This function is called by a \texttt{gen_fsm} when it receives any other message than a synchronous or asynchronous event (or a system message). \texttt{Info} is the received message.

See \texttt{Module:StateName/2} for a description of the other arguments and possible return values.

\texttt{Module:terminate(Reason, StateName, StateData)}

Types:
- \texttt{Reason = normal | shutdown | term()}
- \texttt{StateName = atom()}
- \texttt{StateData = term()}

This function is called by a \texttt{gen_fsm} when it is about to terminate. It should be the opposite of \texttt{Module:init/1} and do any necessary cleaning up. When it returns, the \texttt{gen_fsm} terminates with \texttt{Reason}. The return value is ignored.

\texttt{Reason} is a term denoting the stop reason, \texttt{StateName} is the current state name, and \texttt{StateData} is the state data of the \texttt{gen_fsm}.

\texttt{Reason} depends on why the \texttt{gen_fsm} is terminating. If it is because another callback function has returned a stop tuple \texttt{\{stop,\ldots\}}, \texttt{Reason} will have the value specified in that tuple. If it is due to a failure, \texttt{Reason} is the error reason.

If the \texttt{gen_fsm} is part of a supervision tree and is ordered by its supervisor to terminate, this function will be called with \texttt{Reason=shutdown} if the following conditions apply:

- the \texttt{gen_fsm} has been set to trap exit signals, and
- the shutdown strategy as defined in the supervisor's child specification is an integer timeout value, not \texttt{brutal\_kill}.

Otherwise, the \texttt{gen_fsm} will be immediately terminated.

Note that for any other reason than \texttt{normal} or \texttt{shutdown}, the \texttt{gen_fsm} is assumed to terminate due to an error and an error report is issued using \texttt{error\_logger:format/2}.

\texttt{Module:code\_change(OldVsn, StateName, StateData, Extra) -> \{ok, NextStateName, NewStateData\}}

Types:
- \texttt{OldVsn = undefined | term()}
- \texttt{StateName = NextStateName = atom()}
- StateData = NewStateData = term()
- Extra = term()

This function is called by a gen\_fsm when it should update its state data due to a code replacement, i.e. when the instruction

\{update, Module, Change, PrePurge, PostPurge, Modules\} where

Change=\{advanced, Extra\} has been given to the release handler. See SASL User's Guide for more information.

OldVsn is the vsn attribute of the old version of the callback module Module, or undefined if no such attribute is defined.
StateName is the current state name and StateData the state data of the gen\_fsm.
Extra is the same as in the \{advanced, Extra\} part of the update instruction.
The function should return the new current state name and updated state data.

**SEE ALSO**

supervisor(3), sys(3)
A behaviour module for implementing the server of a client-server relation. A generic server process (gen_server) implemented using this module will have a standard set of interface functions and include functionality for tracing and error reporting. It will also fit into an OTP supervision tree. Refer to OTP Design Principles for more information.

A gen_server assumes all specific parts to be located in a callback module exporting a pre-defined set of functions. The relationship between the behaviour functions and the callback functions can be illustrated as follows:

```
gen_server module           Callback module
----------------- ---------------
gen_server:start           ----- > Module:init/1

gen_server:call

gen_server:multi:call     ----- > Module:handle_call/3

gen_server:cast

gen_server:abcast        ----- > Module:handle_cast/2

-                        ----- > Module:handle_info/2

-                        ----- > Module:terminate/2

-                        ----- > Module:code_change/3
```

If a callback function fails or returns a bad value, the gen_server will terminate.

The sys module can be used for debugging a gen_server.

Note that a gen_server does not trap exit signals automatically, this must be explicitly initiated in the callback module.

Unless otherwise stated, all functions in this module fail if the specified gen_server does not exist or if bad arguments are given.

## Exports

```
start(Module, Args, Options) -> Result
start(ServerName, Module, Args, Options) -> Result
start_link(Module, Args, Options) -> Result
start_link(ServerName, Module, Args, Options) -> Result
```

Types:
- ServerName = {local, Name}  |  {global, Name}
**gen_server**

- **Name** = atom()
- **Module** = atom()
- **Args** = term()
- **Options** = [Option]
  - Option = {debug,Dbgs} | {timeout,Time} | {spawn_opt,SOpts}
- **Dbgs** = [Dbg]
  - Dbg = trace | log | statistics | {log_to_file,FileName} | {install,{Func,FuncState}}
- **SOpts** = [term()]
- **Result** = {ok,Pid} | ignore | {error,Error}
  - **Pid** = pid()
  - **Error** = {already_started,Pid} | term()

Creates a gen_server process which calls Module:init/1 to initialize. To ensure a synchronized start-up procedure, this function does not return until Module:init/1 has returned.

A gen_server started using start_link is linked to the calling process, this function must be used if the gen_server is included in a supervision tree. A gen_server started using start is not linked to the calling process.

If ServerName=local,Name the gen_server is registered locally as Name using register/2. If ServerName=global,Name the gen_server is registered globally as Name using global:register_name/2. If no name is provided, the gen_server is not registered.

Module is the name of the callback module.

**Args** is an arbitrary term which is passed as the argument to Module:init/1.

If the option {timeout,Time} is present, the gen_server is allowed to spend Time milliseconds initializing or it will be terminated and the start function will return {error,timeout}.

If the option {debug,Dbgs} is present, the corresponding sys function will be called for each item in Dbgs. Refer to sys(3) for more information.

If the option {spawn_opt,SOpts} is present, SOpts will be passed as option list to the spawn_opt BIF which is used to spawn the gen_server. Refer to erlang(3) for information about the spawn_opt options.

If the gen_server is successfully created and initialized the function returns {ok,Pid}, where Pid is the pid of the gen_server. If there already exists a process with the specified ServerName the function returns {error,{already_started,Pid}}, where Pid is the pid of that process.

If Module:init/1 fails with Reason, the function returns {error,Reason}. If Module:init/1 returns {stop,Reason} or ignore, the process is terminated and the function returns {error,Reason} or ignore, respectively.

```
call(ServerRef, Request) -> Reply

call(ServerRef, Request, Timeout) -> Reply
```

Types:
- **ServerRef** = Name | {Name,Node} | {global,Name} | pid()
- **Name** = Node = atom()
- **Request** = term()
- **Timeout** = int() > 0 | infinity
• Reply = term()
Makes a synchronous call to the gen_server ServerRef by sending a request and waiting until a reply arrives or a timeout occurs. The gen_server will call Module:handle_call/3 to handle the request.

ServerRef can be:

• the pid,
• Name, if the gen_server is locally registered,
• {Name,Node}, if the gen_server is locally registered at another node, or
• {global,Name}, if the gen_server is globally registered.

Request is an arbitrary term which is passed as one of the arguments to Module:handle_call/3.

Timeout is an integer greater than zero which specifies how many milliseconds to wait for a reply, or the atom infinity to wait indefinitely. Default value is 5000. If no reply is received within the specified time, the function call fails.

The return value Reply is defined in the return value of Module:handle_call/3.

In the case where the gen_server terminates during the handling of the request and the client is linked to the gen_server and trapping exits, the exit message is removed from the client's receive queue before the function call fails.

This behaviour is retained for backwards compatibility only and may change in the future. Note that if the gen_server crashes in between calls, the client must take care of the exit message anyway.

Warning: Under certain circumstances (e.g. ServerRef = {Name,Node}, and Node goes down) the exit message cannot be removed.

multi_call(Name, Request) -> Result
multi_call(Nodes, Name, Request) -> Result
multi_call(Nodes, Name, Request, Timeout) -> Result

Types:
• Nodes = [Node]
• Node = atom()
• Name = atom()
• Request = term()
• Timeout = int() > 0 | infinity
• Result = {Replies,BadNodes}
• Replies = [{Node,Reply}]
• Reply = term()
• BadNodes = [Node]

Makes a synchronous call to all gen_servers locally registered as Name at the specified nodes by first sending a request to every node and then waiting for the replies. The gen_servers will call Module:handle_call/3 to handle the request.

The function returns a tuple {Replies,BadNodes} where Replies is a list of {Node,Reply} and BadNodes is a list of node that either did not exist, or where the gen_server Name did not exist or did not reply.

Nodes is a list of node names to which the request should be sent. Default value is the list of all known nodes [node()|nodes()].
Name is the locally registered name of each gen_server.
Request is an arbitrary term which is passed as one of the arguments to Module:handle_call/3.
Timeout is an integer greater than zero which specifies how many milliseconds to wait for each reply, or the atom infinity to wait indefinitely. Default value is infinity. If no reply is received from a node within the specified time, the node is added to BadNodes.
When a reply Reply is received from the gen_server at a node Node, \{Node,Reply\} is added to Replies. Reply is defined in the return value of Module:handle_call/3.

Warning:
If one of the nodes is running Erlang/OTP R6B or older, and the gen_server is not started when the requests are sent, but starts within 2 seconds, this function waits the whole Timeout, which may be infinity. This problem does not exist if all nodes are running Erlang/OTP R7B or later.

This function does not read out any exit messages like call/2,3 does.
The previously undocumented functions safe_multi_call/2,3,4 were removed in OTP R7B/Erlang 5.0 since this function is now safe, except in the case mentioned above.

\[\text{cast} (\text{ServerRef}, \text{Request}) \rightarrow \text{ok} \]

Types:
- ServerRef = Name | \{Name,Node\} | \{global,Name\} | pid()
- Name = Node = atom()
- Request = term()

Sends an asynchronous request to the gen_server ServerRef and returns ok immediately. The gen_server will call Module:handle_cast/2 to handle the request.

See call/2,3 for a description of ServerRef.
Request is an arbitrary term which is passed as one of the arguments to Module:handle_cast/2.

\[\text{abcast} (\text{Name}, \text{Request}) \rightarrow \text{abcast} \]
\[\text{abcast} (\text{Nodes}, \text{Name}, \text{Request}) \rightarrow \text{abcast} \]

Types:
- Nodes = [Node]
- Node = atom()
- Name = atom()
- Request = term()
Sends an asynchronous request to the gen_servers locally registered as Name at the specified nodes. The function returns immediately and ignores nodes that does not exist, or where the gen_server Name does not exist. The gen_servers will call Module:handle_cast/2 to handle the request. See multi_call/2,3,4 for a description of the arguments.

reply(Client, Reply) -> true

Types:
- Client - see below
- Reply = term()

This function can be used by a gen_server to explicitly send a reply to a client that called call or multi_call, when the reply cannot be defined in the return value of Module:handle_call/3.

Client must be the From argument provided to the callback function. Reply is an arbitrary term, which will be given back to the client as the return value of call or multi_call.

CALLBACK FUNCTIONS

The following functions should be exported from a gen_server callback module.

Exports

Module:init(Args) -> Result

Types:
- Args = term()
- Result = {ok,State} | {ok,State,Timeout} | {stop,Reason} | ignore
- State = term()
- Timeout = int() = 0 | infinity
- Reason = term()

Whenever a gen_server is started using gen_server:start/3,4 or gen_server:start_link/3,4, this function is called by the new process to initialize. Args is the Args argument provided to the start function.

If the initialization is successful, the function should return {ok,State} or {ok,State,Timeout}, where State is the internal state of the gen_server.

If an integer timeout value is provided, a timeout will occur unless a request or a message is received within Timeout milliseconds. A timeout is represented by the atom timeout which should be handled by the handle_info/2 callback function. The atom infinity can be used to wait indefinitely, this is the default value.

If something goes wrong during the initialization the function should return {stop,Reason} where Reason is any term, or ignore.

Module:handle_call(Request, From, State) -> Result
Types:
- Request = term()
- From = {pid(),Tag}
- State = term()
- Result = {reply,Reply,NewState} | {reply,Reply,NewState,Timeout}
- | {noreply,NewState} | {noreply,NewState,Timeout}
- | {stop,Reason,Reply,NewState} | {stop,Reason,NewState}
- Reply = term()
- NewState = term()
- Timeout = int() > 0 | infinity
- Reason = term()

Whenever a gen_server receives a request sent using gen_server:call/2,3 or gen_server:multi_call/2,3,4, this function is called to handle the request. Request is the Request argument provided to call or multi_call. From is a tuple {Pid,Tag} where Pid is the pid of the client and Tag is a unique tag. State is the internal state of the gen_server.

If the function returns {reply,Reply,NewState} or {reply,Reply,NewState,Timeout}, Reply will be given back to From as the return value of call or included in the return value of multi_call. The gen_server then continues executing with the possibly updated internal state NewState. See Module:init/1 for a description of Timeout.

If the function returns {noreply,NewState} or {noreply,NewState,Timeout}, the gen_server will continue executing with NewState. Any reply to From must be given explicitly using gen_server:reply/2.

If the function returns {stop,Reason,Reply,NewState}, Reply will be given back to From. If the function returns {stop,Reason,NewState}, any reply to From must be given explicitly using gen_server:reply/2. The gen_server will then call Module:terminate(Reason,NewState) and terminate.

Module:handle_cast(Request, State) -> Result

Types:
- Request = term()
- State = term()
- Result = {noreply,NewState} | {noreply,NewState,Timeout}
- | {stop,Reason,NewState}
- NewState = term()
- Timeout = int() > 0 | infinity
- Reason = term()

Whenever a gen_server receives a request sent using gen_server:cast/2 or gen_server:abcast/2,3, this function is called to handle the request. See Module:handle_call/3 for a description of the arguments and possible return values.

Module:handle_info(Info, State) -> Result

Types:
• Info = timeout | term()
• State = term()
• Result = {noreply, NewState} | {noreply, NewState, Timeout}
• | {stop, Reason, NewState}
• NewState = term()
• Timeout = int() > 0 | infinity
• Reason = normal | term()

This function is called by a gen_server when a timeout occurs or when it receives any other message than a synchronous or asynchronous request (or a system message). Info is either the atom timeout, if a timeout has occurred, or the received message.

See Module:handle_call/3 for a description of the other arguments and possible return values.

Module:terminate(Reason, State)

Types:
• Reason = normal | shutdown | term()
• State = term()

This function is called by a gen_server when it is about to terminate. It should be the opposite of Module:init/1 and do any necessary cleaning up. When it returns, the gen_server terminates with Reason. The return value is ignored.

Reason is a term denoting the stop reason and State is the internal state of the gen_server.

Reason depends on why the gen_server is terminating. If it is because another callback function has returned a stop tuple {stop,..}, Reason will have the value specified in that tuple. If it is due to a failure, Reason is the error reason.

If the gen_server is part of a supervision tree and is ordered by its supervisor to terminate, this function will be called with Reason=shutdown if the following conditions apply:

• the gen_server has been set to trap exit signals, and
• the shutdown strategy as defined in the supervisor’s child specification is an integer timeout value, not brutal_kill.

Otherwise, the gen_server will be immediately terminated.

Note that for any other reason than normal or shutdown, the gen_server is assumed to terminate due to an error and an error report is issued using error_logger:format/2.

Module:code_change(OldVsn, State, Extra) -> {ok, NewState}

Types:
• OldVsn = undefined | term()
• State = NewState = term()
• Extra = term()
This function is called by a gen_server when it should update its internal state due to code replacement, i.e. when the instruction
\{update,Module,Change,PrePurge,PostPurge,Modules\} where
Change=\{advanced,Extra\} has been given to the release handler. See SASL User's Guide for more information.

OldVsn is the \texttt{vsn} attribute of the old version of the callback module \texttt{Module}, or undefined if no such attribute is defined.

State is the internal state of the gen_server.

Extra is the same as in the \{advanced,Extra\} part of the update instruction.

The function should return the updated internal state.

io

Erlang Module

This module provides an interface to standard Erlang I/O servers. The output functions all return ok if they are successful, or exit if they are not. In the following description, a parameter within square brackets means that that parameter is optional. [IoDevice,] is such an example. If included, it must be the Pid of a process which handles the I/O protocols. This is often the IoDevice returned by file:open/2 (see file). For a description of the I/O protocols refer to Armstrong, Virding and Williams, ‘Concurrent Programming in Erlang’, Chapter 13.

Exports

put_chars([IoDevice,] Chars)

Writes the characters Chars to the standard output (IoDevice). Chars is a list of characters. The list is not necessarily flat.

nl([IoDevice])

Writes new line to the standard output (IoDevice).

get_chars([IoDevice,] Prompt, Count)

Gets Count characters from standard input (IoDevice), prompting it with Prompt. It returns:

ListOfChars Returns the input characters, if they are less than Count.

eof End of file was encountered.

get_line([IoDevice,] Prompt)

Gets a line from the standard input (IoDevice), prompting it with Prompt. It returns:

ListOfChars The characters in the line terminated by a LF unless the line read was the last line of the file and was not terminated by LF.

eof End of file was encountered.

write([IoDevice,] Term)

Writes the term Term to the standard output (IoDevice).

read([IoDevice,] Prompt)
Reads a term from the standard input (IoDevice), prompting it with Prompt. It returns:

- **ok, Term** The parsing was successful.
- **error, ErrorInfo** The parsing failed.
- **eof** End of file was encountered.

`fwrite(Format)`
`format(Format)`
Equivalent to `fwrite(Format, [])`.

`fwrite([IoDevice,] Format, Arguments)`
`format([IoDevice,] Format, Arguments)`
Writes the list of items in Arguments on the standard output (IoDevice) in accordance with Format. Format is a list of plain characters which are copied to the output device, and control sequences which cause the arguments to be printed. If Format is an atom, it is first converted to a list with the aid of `atom_to_list/1`. Arguments is the list of items to be printed.

```prolog
> io:fwrite("Hello world!
", []).
Hello world
ok
```

The general format of a control sequence is `~F.P.PadC`. The character `C` determines the type of control sequence to be used, `F` and `P` are optional numeric arguments. If `F`, `P`, or Pad is `*`, the next argument in Arguments is used as the numeric value of `F` or `P`.

- **F** is the field width of the printed argument. A negative value means that the argument will be left justified within the field, otherwise it will be right justified. If no field width is specified, the required print width will be used. If the field width specified is too small, then the whole field will be filled with `*` characters.
- **P** is the precision of the printed argument. A default value is used if no precision is specified. The interpretation of precision depends on the control sequences. Unless otherwise specified, the argument within is used to determine print width.
- **Pad** is the padding character. This is the character used to pad the printed representation of the argument so that it conforms to the specified field width and precision. Only one padding character can be specified and, whenever applicable, it is used for both the field width and precision. The default padding character is ' ' (space).

The following control sequences are available:

- `~` The character ~ is written.
- `c` The argument is a number that will be interpreted as an ASCII code. The precision is the number of times the character is printed and it defaults to the field width, which in turn defaults to one. The following example illustrates:

  ```prolog
  > io:fwrite("|~10.5c|~10.5c|~5c|~n", [$a, $b, $c]).
  | aaaaa|aaaaa |ccccc|
  ok
  ```

- `f` The argument is a float which is written as [-]ddd.ddd, where the precision is the number of digits after the decimal point. The default precision is 6.
The argument is a float which is written as \[-\]d.ddde+-ddd, where the precision is the number of digits written. The default precision is 6.

The argument is a float which is written as f, if it is > 0.1, and < $10^{-4}$. Otherwise, it is written as e. The precision is the number of significant digits. It defaults to 6. There must always be a sufficient number of digits for printing a correct floating point representation of the argument.

Prints the argument with the string syntax. The argument is a list of character codes (possibly not a flat list), or an atom. The characters are printed without quotes. In this format, the printed argument is truncated to the given precision and field width.

This format can be used for printing any object and truncating the output so it fits a specified field:

```erlang
> io:fwrite("|~10w|~n", [{hey, hey, hey}]).
|**********|
ok
> io:fwrite("|~10s|~n", [io_lib:write({hey, hey, hey})]).
[{hey, hey, h|
ok
```

Writes data with the standard syntax. This is used to output Erlang terms. Atoms are printed within quotes if they contain embedded non-printable characters, and floats are printed in the default g format.

Writes the data with standard syntax in the same way as \~w, but breaks terms whose printed representation is longer than one line into many lines and indents each line sensibly. It also tries to detect lists of printable characters and to output these as strings. For example:

```erlang
> T = [{attributes,[[{id,age,1.50000},{mode,explicit},
                     {typename,"INTEGER"}],
                   [{id,cho},{mode,explicit},{typename,'Cho'}]]},
       {typename,'Person'},
       {tag,{'PRIVATE',3}},
       {mode,implicit}].
```

```erlang
> io:fwrite("~w~n", [T]).
[{attributes,[[{id,age,1.50000},{mode,explicit},
              {typename,73,78,84,69,71,69,82}]],
  [{id,cho},{mode,explicit},{typename,'Cho'}]},
  {typename,'Person'},
  {tag,{'PRIVATE',3}},
  {mode,implicit}]
ok
> io:fwrite("~p~n", [T]).
[{attributes,[[{id,age,1.50000},
              {mode,explicit}],
              {typename,"INTEGER"}],
  [{id,cho},{mode,explicit},{typename,'Cho'}]]},
  {typename,'Person'},
  {tag,{'PRIVATE',3}},
  {mode,implicit}]
ok
```

The field width specifies the maximum line length. It defaults to 80. The precision specifies the initial indentation of the term. It defaults to the number of characters printed on this line in the same call to io:fwrite or io:format. For example, using T above:
> io:fwrite("Here T = \~p\n", [T]).
Here T = [{attributes,[[{id,age,1.50000},
    {mode,explicit},
    {typename,"INTEGER"}],
   [{id,cho},{mode,explicit},
    {typename,'Cho'}]}],
   {typename,'Person'},
   {tag,{'PRIVATE',3}},
   {mode,implicit}]
ok

W Writes data in the same way as ~w, but takes an extra argument which is the maximum depth to which terms are printed. Anything below this depth is replaced with ... For example, using T above:

> io:fwrite("\~W\n", [T,9]).
[{attributes,[[{id,age,1.50000},{mode,explicit},{typename|
  ...}],[{id,cho},{mode...},{...}]}],{typename,'Person'},{t
tag,{'PRIVATE',3}},{mode,implicit}]
ok

If the maximum depth has been reached, then it is impossible to read in the resultant output. Also, the |... form in a tuple denotes that there are more elements in the tuple but these are below the print depth.

P Writes data in the same way as ~p, but takes an extra argument which is the maximum depth to which terms are printed. Anything below this depth is replaced with ... For example:

> io:fwrite("\~P\n", [T,9]).
[{attributes,[[{id,age,1.50000},{mode,explicit},
   {typename|...}],[{id,cho},{mode|...},{...}]}],{typename,'Person'},{t
tag,{'PRIVATE',3}},{mode,implicit}]
ok

n Writes a new line.
i Ignores the next term.

Returns:

ok The formatting succeeded.

If an error occurs, there is no output. For example:

> io:fwrite("\~s \~w \~i \~w \~c \n",[\'abc def\', \'abc def\',
  {foo, 1},{foo, 1}, 65]).
abc def 'abc def' {foo, 1} A
ok

> io:fwrite("\~s", [65]).
** exited: {badarg,[[io,format,[<0.21.0>,"\~s","A"]],[erl_eval,expr,3],[erl_eval,exprs,4],[shell,eval_loop,2]]} **
In this example, an attempt was made to output the single character ‘65’ with the aid of the string formatting directive “~s”.

The two functions fwrite and format are identical. The old name format has been retained for backwards compatibility, while the new name fwrite has been added as a logical complement to fread.

fwrite([IoDevice], Prompt, Format)

Reads characters from the standard input (IoDevice), prompting it with Prompt. Interprets the characters in accordance with Format. Format is a list of control sequences which directs the interpretation of the input.

Format may contain:

- White space characters (SPACE, TAB and NEWLINE) which cause input to be read to the next non-white space character.
- Ordinary characters which must match the next input character.
- Control sequences, which have the general format “~*FC”. The character * is an optional return suppression character. It provides a method to specify a field which is to be omitted. F is the field width of the input field and C determines the type of control sequence.

Unless otherwise specified, leading white-space is ignored for all control sequences. An input field cannot be more than one line wide. The following control sequences are available:

- A single ~ is expected in the input.
- A decimal integer is expected.
- A floating point number is expected. It must follow the Erlang floating point number syntax.
- A string of non-white-space characters is read. If a field width has been specified, this number of characters are read and all trailing white-space characters are stripped. An Erlang string (list of characters) is returned.
- Similar to s, but the resulting string is converted into an atom.
- The number of characters equal to the field width are read (default is 1) and returned as an Erlang string. However, leading and trailing white-space characters are not omitted as they are with s. All characters are returned.
- Returns the number of characters which have been scanned up to that point, including white-space characters.

It returns:

{ok, InputList} The read was successful and InputList is the list of successfully matched and read items.
{error, What} The read operation failed and the parameter What can be used as argument to report_error/1 to produce an error message.
eof End of file was encountered.

Examples:
> io:fread('enter>', "f-f-f").
enter>1.9 35.5e3 15.0
{ok, [1.90000, 3.55000e+4, 15.0000]}
> io:fread('enter>', "10f-d").
enter> 5.67899
{ok, [5.67800, 99]}
> io:fread('enter>', "s10c").
enter>: alan : joe :
{ok, ["alan", "joe "]}

scan_erl_exprs(Prompt)
scan_erl_exprs([IoDevice,] Prompt, StartLine)

Reads data from the standard input (IoDevice), prompting it with Prompt. Reading
starts at line number StartLine (1). The data is tokenized as if it were a sequence of
Erlang expressions until a final ' .' is reached. This token is also returned. It returns:

{ok, Tokens, EndLine} The tokenization succeeded.
{error, ErrorInfo, EndLine} An error occurred.
{eof, EndLine} End of file was encountered.

Example:
> io:scan_erl_exprs('enter>').
enter>abc(), "hey".
{ok, [{atom, 1, abc}, {'(', 1}, {')', 1}, {', ', 1},
    {string, 1, "hey"}, {dot, 1}]], 2}
> io:scan_erl_exprs('enter>').
enter>1.0er.
{error, {1, erl_scan, float}, 2}

scan_erl_form(Prompt)
scan_erl_form(IoDevice, Prompt[, StartLine])

Reads data from the standard input (IoDevice), prompting it with Prompt. Starts
reading at line number StartLine (1). The data is tokenized as if it were an Erlang form
- one of the valid Erlang expressions in an Erlang source file - until a final ' .' is reached.
This last token is also returned. The return values are the same as for scan_erl_exprs.

parse_erl_exprs(Prompt)
parse_erl_exprs(IoDevice, Prompt[, StartLine])

Reads data from the standard input (IoDevice), prompting it with Prompt. Starts
reading at line number StartLine (1). The data is tokenized and parsed as if it were a
sequence of Erlang expressions until a final ' .' is reached. It returns:

{ok, ExpressionList, EndLine} The parsing was successful.
{error, ErrorInfo, EndLine} An error occurred.
{eof, EndLine} End of file was encountered.

Example:
parse Erlang expressions

```erlang
> io:parse_erl_exprs('enter>').
enter>abc(), "hey".
{ok, [{call, 1, [], abc, []}, {string, 1, "hey"}], 2}
> io:parse_erl_exprs('enter>').
enter>abc("hey").
{error, {1, erl_parse, {before, {terminator,') '}, {dot, 1}}}, 2}
```

```erlang
parse.erl
```

```erlang
parse.erl
```

```erlang
def parse.erl form(Prompt)
def parse.erl form(IoDevice, Prompt[, StartLine])

Reads data from the standard input (IoDevice), prompting it with Prompt Starts reading at line number StartLine (1). The data is tokenized and parsed as if it were an Erlang form - one of the valid Erlang expressions in an Erlang source file - until a final '.' is reached. It returns:

{ok, Form, EndLine} The parsing was successful.
{error, ErrorInfo, EndLine} An error occurred.
{eof, EndLine} End of file was encountered.

Standard Input/Output

All Erlang processes have a default standard IO device. This device is used when no IoDevice argument is specified in the IO calls. However, it is sometimes desirable to use an explicit IoDevice argument which refers to the default IO device. The atom standardio has this special meaning. The following example illustrates this:

```erlang
> io:read('enter>').
enter>foo.
{term, foo}
> io:read(standard_io, 'enter>').
enter>bar.
{term, bar}
```

There is always a process registered under the name of user. This can be used for sending output to the user.

Error Information

The ErrorInfo mentioned above is the standard ErrorInfo structure which is returned from all IO modules. It has the following format:

```erlang
{ErrorLine, Module, ErrorDescriptor}
```

A string which describes the error is obtained with the following call:

```erlang
apply(Module, format_error, ErrorDescriptor)
```
This module contains functions for converting to and from strings (lists of characters).
They are used for implementing the functions in the io module. There is no guarantee
that the character lists returned from some of the functions are flat, they can be deep.
lists:flatten/1 is used for generating flat lists.

Exports

nl()
Returns a character list which represents a new line character.

write(Term)
write(Term, Depth)
Returns a character list which represents Term. The Depth (-1) argument controls the
depth of the structures written. When the specified depth is reached, everything below
this level is replaced by "...". For example:
> lists:flatten(io_lib:write([{1,[2],[3],[4,5],6,7,8,9]})).
"{1,[2],[3],[4,5],6,7,8,9}"
> lists:flatten(io_lib:write([{1,[2],[3],[4,5],6,7,8,9}, 5]).
"{1,[2],[3],[4|...],6|...}"

print(Term)
print(Term, Column, LineLength, Depth)
Also returns a list of characters which represents Term, but breaks representations which
are longer than one line into many lines and indents each line sensibly. It also tries to
detect and output lists of printable characters as strings. Column is the starting column
(1), LineLength the maximum line length (80), and Depth the maximum print depth.

fwrite(Format, Data)
format(Format, Data)
Returns a character list which represents Data formatted in accordance with Format.
Refer to io [page 165] for a detailed description of the available formatting options. A
fault is generated if there is an error in the format string or argument list.

fread(Format, String)
Tries to read String in accordance with the control sequences in Format. Refer to io [page 165] for a detailed description of the available formatting options. It is assumed that String contains whole lines. It returns:

{ok, InputList, LeftOverChars} The string was read. InputList is the list of successfully matched and read items, and LeftOverChars are the input characters not used.

{more, RestFormat, Nchars, InputStack} The string was read, but more input is needed in order to complete the original format string. RestFormat is the remaining format string, Nchars the number of characters scanned, and InputStack is the reversed list of inputs matched up to that point.

{error, What} An error occurred which can be formatted with the call format_error/1.

Example:

> io_lib:fread("~f~f~f", "15.6 17.3e-6 24.5").
{ok, [15.6000, 1.73000e-5, 24.5000], []}

fread(Continuation, CharList, Format)

This is the re-entrant formatted reader. It returns:

{done, Result, LeftOverChars} The input is complete. The result is one of the following:

{ok, InputList} The string was read. InputList is the list of successfully matched and read items, and LeftOverChars are the remaining characters.

eof End of file has been encountered. LeftOverChars are the input characters not used.

{error, What} An error occurred, which can be formatted with the call format_error/1.

{more, Continuation} More data is required to build a term. Continuation must be passed to <c>fread/3, when more data becomes available.

write_atom(Atom)

Returns the list of characters needed to print the atom Atom.

write_string(String)

Returns the list of characters needed to print String as a string.

write_char(Integer)

Returns the list of characters needed to print a character constant.

indentation(String, StartIndent)

Returns the indentation if String has been printed, starting at Indentation.
Returns true if CharList is a list of characters, otherwise it returns false.

```
deep_char_list(CharList)
```

Returns true if CharList is a deep list of characters, otherwise it returns false.

```
printable_list(CharList)
```

Returns true if CharList is a list of printable characters, otherwise it returns false.

**Notes**

The module `io_lib` also uses the extra modules `io_lib_format`, `io_lib_fread`, and `io_lib_pretty`. All external interfaces exist in `io_lib`.

Users are strongly advised not to access the other modules directly.

**Note:**

Any undocumented functions in `io_lib` should not be used.

The continuation of the first call to the re-entrant input functions must be `. Refer to Armstrong, Virding, Williams, 'Concurrent Programming in Erlang', Chapter 13 for a complete description of how the re-entrant input scheme works.
lib

Erlang Module

The module `lib` provides the following useful library functions.

Exports

`flush() -> void()`
Flushes the message buffer of the current process.

`error_message(Format, Args)`
Prints error message `Args` in accordance with `Format` in the normal way.

`progname() -> atom()`
Returns the name of the script that starts the current Erlang session.

`nonl(List1)`
Removes the last newline character, if any, in `List`.

`send(To, Msg)`
This function makes it possible to send a message through `apply`.

`sendw(To, Msg)`
As `send/2`, but waits for an answer. It is implemented as follows:

```erlang
sendw(To, Msg) ->
  To ! {self(), Msg},
  receive
    Reply -> Reply
  end.
```

The message returned is not necessarily a reply to the message sent.

Warning

This module is retained for compatibility. It may disappear without warning in a future release.
lists
Erlang Module

This module contains functions for list processing. The functions are organized in two groups: those in the first group perform a particular operation on one or several lists, whereas those in the second group perform use a user-defined function (given as the first argument) to perform an operation on one list.

Exports

append(ListOfLists) -> List1
Types:
- ListOfLists = [List]
- List = List1 = [term()]
Returns a list in which all the sub-lists of ListOfLists have been appended. For example:
> lists:append([[1, 2, 3], [a, b], [4, 5, 6]]).
[1, 2, 3, a, b, 4, 5, 6]
The result need not be a proper list. The last parameter may be of any datatype and will be the tail in the resulting list. An example:
> lists:append([[a,b],c]).
[a,b|c]
The atom c will be the tail of the list and the list is therefore not proper (a proper list ends with []). As a parameter of [] is ignored this example is also valid (although probably useless):
lists:append([],d)).

append(List1, List2) -> List3
Types:
- List1 = List2 = List3 = [term()]
Returns a new list List3 which is made from the elements of List1 followed by the elements of List2. For example:
> lists:append("abc", "def").
"abcdef".
lists:append(A,B) is equivalent to A ++ B.
The behaviour regarding improper lists is identical to the behaviour of lists:append/1
concat(Things) -> string()

Types:
  • Things = [Thing]
  • Thing = atom() | integer() | float() | string()

Concatenates the ASCII list representation of the elements of Things. The elements of Things can be atoms, integers, floats or strings.

> lists:concat([doc, '/', file, '.', 3]).
"doc/file.3"

delete(Element, List1) -> List2

Types:
  • List1 = List2 = [Element]
  • Element = term()

Returns a copy of List1, but the first occurrence of Element, if present, is deleted.

duplicate(N, Element) -> List

Types:
  • N = int()
  • List = [Element]
  • Element = term()

Returns a list which contains N copies of the term Element.

Note:
N must be an integer >= 0. For example:

> lists:duplicate(5, xx).
[xx, xx, xx, xx, xx]

flatlength(DeepList) -> int()

Equivalent to length(flatten(DeepList)), but more efficient.

flatten(DeepList) -> List

Types:
  • DeepList = [term() | DeepList]

Returns a flattened version of DeepList.

flatten(DeepList, Tail) -> List

Types:
  • DeepList = [term() | DeepList]
  • Tail = [term()]

Returns a flattened version of DeepList with the tail Tail appended.
keydelete(Key, N, TupleList1) -> TupleList2

Types:
- TupleList1 = TupleList2 = [tuple()]
- N = int()
- Key = term()

Returns a copy of TupleList1 where the first occurrence of a tuple whose Nth element is Key is deleted, if present.

keymember(Key, N, TupleList) -> bool()

Types:
- TupleList = [tuple()]
- N = int()
- Key = term()

Searches the list of tuples TupleList for a tuple whose Nth element is Key.

keymerge(N, List1, List2)

Types:
- N = int()
- List1 = List2 = [tuple()]

Returns the sorted list formed by merging List1 and List2. The merge is performed on the Nth element of each tuple. Both List1 and List2 must be key-sorted prior to evaluating this function; otherwise the order of the elements in the result will be undefined. When elements in the input lists compare equal, elements from List1 are picked before elements from List2.

keyreplace(Key, N, TupleList1, NewTuple) -> TupleList2

Types:
- Key = term()
- N = int()
- TupleList1 = TupleList2 = [tuple()]
- NewTuple = tuple()

Returns a list of tuples. In this list, a tuple is replaced by the tuple NewTuple. This tuple is the first tuple in the list where the element number N is equal to Key.

keysearch(Key, N, TupleList) -> Result

Types:
- TupleList = [tuple()]
- N = int()
- Key = term()
- Result = {value, tuple()} | false

Searches the list of the tuples TupleList for Tuple whose Nth element is Key. Returns {value, Tuple} if such a tuple is found, or false if no such tuple is found.

keysort(N, List1) -> List2
Types:
- \( N = \text{int()}
- \text{List1 = List2 = [tuple()]

Returns a list containing the sorted elements of \text{List1}. \text{TupleList1} must be a list of tuples, and the sort is performed on the \( N \)th element of the tuple. The sort is stable.

\text{last(List)} \rightarrow \text{Element}

Types:
- \text{List} = [\text{Element}]
- \text{Element} = \text{term()}

Returns the last element in \text{List}.

\text{max(List)} \rightarrow \text{Max}

Types:
- \text{List} = [\text{Element}]
- \text{Element} = \text{Max} = \text{term()}

Returns the maximum element of \text{List}.

\text{member(Element, List)} \rightarrow \text{bool()}

Types:
- \text{List} = [\text{Element}]
- \text{Element} = \text{term()}

Returns \text{true} if \text{Element} is contained in the list \text{List}, otherwise \text{false}.

\text{merge(ListOfLists)} \rightarrow \text{List1}

Types:
- \text{ListOfLists} = [\text{List}]
- \text{List} = \text{List1} = \text{[term()]}

Returns the sorted list formed by merging all the sub-lists of \text{ListOfLists}. All sub-lists must be sorted prior to evaluating this function.

\text{merge(List1, List2)} \rightarrow \text{List3}

Types:
- \text{List1} = \text{List2} = \text{List3} = \text{[term()]}

Returns the sorted list formed by merging \text{List1} and \text{List2}. Both \text{List1} and \text{List2} must be sorted prior to evaluating this function.

\text{merge(Fun, List1, List2)} \rightarrow \text{List}

Types:
- \text{List} = \text{List1} = \text{List2} = [\text{Element}]
- \text{Fun} = \text{fun(Element, Element)} \rightarrow \text{bool()}
- \text{Element} = \text{term()}

\text{STDLIB Reference Manual}  
lists  
179
Returns the sorted list formed by merging List1 and List2. Both List1 and List2 must be sorted according to the ordering function Fun prior to evaluating this function. Fun(A,B) should return true if A comes before B in the ordering, false otherwise.

merge3(List1, List2, List3) -> List4

Types:
- List1 = List2 = List3 = List4 = [term()]

Returns the sorted list formed by merging List1, List2 and List3. All of List1, List2 and List3 must be sorted prior to evaluating this function.

min(List) -> Min

Types:
- List = [Element]
- Element = Max = term()

Returns the minimum element of List.

nth(N, List) -> Element

Types:
- N = int()
- List = [Element]
- Element = term()

Returns the Nth element of the List. For example:

> lists:nth(3, [a, b, c, d, e]). c

tnth(N, List1) -> List2

Types:
- N = int()
- List1 = List2 = [Alpha]

Returns the Nt tail of List. For example:

> lists:nthtail(3, [a, b, c, d, e]). [d, e]

prefix(List1, List2) -> bool()

Types:
- List1 = List2 = [term()]

Returns true if List1 is a prefix of List2, otherwise false.

reverse(List1) -> List2

Types:
- List1 = List2 = [term()]

Returns a list with the top level elements in List1 in reverse order.
reverse(List1, List2) -> List3
Types:
- List1 = List2 = List3 = [term()]
Returns a list where List1 has been reversed and appended to the beginning of List2. Equivalent to reverse(List1) ++ List2. For example:
> lists:reverse([1, 2, 3, 4], [a, b, c]).
[4, 3, 2, 1, a, b, c]

seq(From, To) -> [int()]
seq(From, To, Incr) -> [int()]
Types:
- From = To = Incr = int()
Returns a sequence of integers which starts with From and contains the successive results of adding Incr to the previous element, until To has been reached or passed (in the latter case, To is not an element of the sequence). If To-From has a different sign from Incr, or if Incr = 0 and From is different from To, an error is signalled (this implies that the result is never an empty list - the first element is always From).
seq(From, To) is equivalent to seq(From, To, 1).
Examples:
> lists:seq(1, 10).
[1, 2, 3, 4, 5, 6, 7, 8, 9, 10]
> lists:seq(1, 20, 3).
[1, 4, 7, 10, 13, 16, 19]
> lists:seq(1, 1, 0).
[1]

sort(List1) -> List2
Types:
- List1 = List2 = [term()]
Returns a list which contains the sorted elements of List1.

sort(Fun, List1) -> List2
Types:
- List1 = List2 = [Element]
- Fun = fun(Element, Element) -> bool()
- Element = term()
Returns a list which contains the sorted elements of List1, according to the ordering function Fun. Fun(A,B) should return true if A comes before B in the ordering, false otherwise.

sublist(List, N) -> List1
Types:
List1 = List2 = [term()]
• N = int()

Returns the first N elements of List. It is not an error for N to exceed the length of the list when List is a proper list - in that case the whole list is returned.

sublist(List1, Start, Length) -> List2

Types:
• List1 = List2 = [term()]
• Start = End = int()

Returns the sub-list of List starting at Start of length Length. Terminates with a runtime failure if Start is not in List, but a sub-list of a length less than Length is accepted. Start is considered to be in List if Start >= 1 and Start <= length(List)+1.

subtract(List1, List2) -> List3

Types:
• List1 = List2 = List3 = [term()]

Returns a new list List3 which is a copy of List1, subjected to the following procedure: for each element in List2, its first occurrence in List1 is removed. For example:

> lists:subtract("123212", "212").
"312".
lists:subtract(A,B) is equivalent to A -- B.

suffix(List1, List2) -> bool()

Returns true if List1 is a suffix of List2, otherwise false.

sum(List) -> number()

Types:
• List = [number()]

Returns the sum of the elements in List.

ukeymerge(N, List1, List2)

Types:
• N = int()
• List1 = List2 = [tuple()]

Returns the sorted list formed by merging List1 and List2 while removing consecutive duplicates. The merge is performed on the Nth element of each tuple. Both List1 and List2 must be key-sorted prior to evaluating this function; otherwise the order of the elements in the result will be undefined. When elements in the input lists compare equal, elements from List1 are picked before elements from List2.

ukeysort(N, List1) -> List2

Types:
• N = int()
• List1 = List2 = [tuple()]

Returns a list containing the sorted elements of List1 with consecutive duplicates removed. TupleList1 must be a list of tuples, and the sort is performed on the \( n \)th element of the tuple. The sort is stable.

\texttt{umerge(ListOfLists)} \rightarrow \texttt{List1}

Types:
• ListOfLists = [List]
• List = List1 = [term()]

Returns the sorted list formed by merging all the sub-lists of ListOfLists while removing duplicates. All sub-lists must be sorted and contain no duplicates prior to evaluating this function.

\texttt{umerge(List1, List2)} \rightarrow \texttt{List3}

Types:
• List1 = List2 = List3 = [term()]

Returns the sorted list formed by merging List1 and List2 while removing duplicates. Both List1 and List2 must be sorted and contain no duplicates prior to evaluating this function.

\texttt{umerge(Fun, List1, List2)} \rightarrow \texttt{List}

Types:
• List = List1 = List2 = [Element]
• Fun = fun(Element, Element) \rightarrow \texttt{bool()}
• Element = \texttt{term()}

Returns the sorted list formed by merging List1 and List2 while removing consecutive duplicates. Both List1 and List2 must be sorted according to the ordering function Fun prior to evaluating this function. Fun(A, B) should return \texttt{true} if A comes before B in the ordering, \texttt{false} otherwise.

\texttt{umerge3(List1, List2, List3)} \rightarrow \texttt{List4}

Types:
• List1 = List2 = List3 = List4 = [term()]

Returns the sorted list formed by merging List1, List2 and List3 while removing duplicates. All of List1, List2 and List3 must be sorted and contain no duplicates prior to evaluating this function.

\texttt{usort(List1)} \rightarrow \texttt{List2}

Types:
• List1 = List2 = [term()]

Returns a list which contains the sorted elements of List1 without duplicates.

\texttt{usort(Fun, List1)} \rightarrow \texttt{List2}
Types:
- List1 = List2 = [Element]
- Fun = fun(Element, Element) -> bool()
- Element = term()

Returns a list which contains the sorted elements of List1 with consecutive duplicates removed, according to the ordering function Fun. Fun(A,B) should return true if A comes before B in the ordering, false otherwise.

all(Pred, List) -> bool()
Types:
- Pred = fun(A) -> bool()
- List = [A]
Returns true if all elements X in List satisfy Pred(X).

any(Pred, List) -> bool()
Types:
- Pred = fun(Element) -> bool()
- List = [Element]
- Element = term()
Returns true if any of the elements in List satisfies Pred.

dropwhile(Pred, List1) -> List2
Types:
- Pred = fun(A) -> bool()
- List1 = List2 = [A]
Drops elements X from List1 while Pred(X) is true and returns the remaining list.

filter(Pred, List1) -> List2
Types:
- Pred = fun(A) -> bool()
- List1 = List2 = [A]
List2 is a list of all elements X in List1 for which Pred(X) is true.

flatmap(Function, List1) -> Element
Types:
- Function = fun(A) -> B
- List1 = [A]
- Element = [B]
flatmap behaves as if it had been defined as follows:
flatmap(Func, List) ->
    append(map(Func, List))

foldl(Function, Acc0, List) -> Acc1
Types:
- Function = fun(A, AccIn) -> AccOut
- List = [A]
- Acc0 = Acc1 = AccIn = AccOut = term()

Acc0 is returned if the list is empty. For example:

```erlang
> lists:foldl(fun(X, Sum) -> X + Sum end, 0, [1,2,3,4,5]).
15
> lists:foldl(fun(X, Prod) -> X * Prod end, 1, [1,2,3,4,5]).
120
```

foldr(Function, Acc0, List) -> Acc1

Types:
- Function = fun(A, AccIn) -> AccOut
- List = [A]
- Acc0 = Acc1 = AccIn = AccOut = term()

Calls Function on successive elements of List together with an extra argument Acc (short for accumulator). Function must return a new accumulator which is passed to the next call. Acc0 is returned if the list is empty. foldr differs from foldl in that the list is traversed “bottom up” instead of “top down”. foldl is tail recursive and would usually be preferred to foldr.

foreach(Function, List) -> void()

Types:
- Function = fun(A) -> void()
- List = [A]

Applies the function Function to each of the elements in List. This function is used for its side effects and the evaluation order is defined to be the same as the order of the elements in the list.

map(Func, List1) -> List2

Types:
- Func = fun(A) -> B
- List1 = [A]
- List2 = [B]

map takes a function from As to Bs, and a list of As and produces a list of Bs by applying the function to every element in the list. This function is used to obtain the return values. The evaluation order is implementation dependent.

mapfoldl(Function, Acc0, List1) -> {List2, Acc}

Types:
- Function = fun(A, AccIn) -> {B, AccOut}
- Acc0 = Acc1 = AccIn = AccOut = term()
- List1 = [A]
- List2 = [B]
mapfold combines the operations of \texttt{map} and \texttt{foldl} into one pass. For example, we could sum the elements in a list and double them at the same time:

\begin{verbatim}
> lists:mapfoldl(fun(X, Sum) -> {2*X, X+Sum} end,
0, [1,2,3,4,5]).
{[2,4,6,8,10],15}
\end{verbatim}

\textbf{mapfoldr} (\texttt{Function}, \texttt{Acc0}, \texttt{List1}) \rightarrow \{\texttt{List2}, \texttt{Acc}\}

Types:
- \texttt{Function = fun(A, \texttt{AccIn}) \rightarrow \{B, \texttt{AccOut}\}}
- \texttt{Acc0 = Acc1 = \texttt{AccIn} = \texttt{AccOut} = \texttt{term()}}
- \texttt{List1 = [A]}
- \texttt{List2 = [B]}

\texttt{mapfold} combines the operations of \texttt{map} and \texttt{foldr} into one pass.

\textbf{splitwith} (\texttt{Pred}, \texttt{List}) \rightarrow \{\texttt{List1}, \texttt{List2}\}

Types:
- \texttt{Pred = fun(A) \rightarrow \texttt{bool()}}
- \texttt{List = List1 = List2 = [A]}

Partitions \texttt{Lists} into \texttt{List1} and \texttt{List2} according to \texttt{Pred}.

\texttt{splitwith} behaves as if it had been defined as follows:

\begin{verbatim}
splitwidth(Pred, List) \rightarrow 
{takewhile(Pred, List), dropwhile(Pred, List)}.
\end{verbatim}

Note also that \texttt{List == List1 ++ List2}.

\textbf{takewhile} (\texttt{Pred}, \texttt{List1}) \rightarrow \texttt{List2}

Types:
- \texttt{Pred = fun(A) \rightarrow \texttt{bool()}}
- \texttt{List1 = List2 = [A]}

Returns the longest prefix of \texttt{List1} for which all elements \texttt{X} in \texttt{List1} satisfy \texttt{Pred(X)}.

\textbf{Relics}

Some of the exported functions in \texttt{lists.erl} are not documented. In particular, this applies to a number of \texttt{maps} and \texttt{folds} which have an extra argument for environment passing. These functions are no longer needed because Erlang 4.4 and later releases have \textbf{Funs}.

\textbf{Note:}

Any undocumented functions in \texttt{lists} should not be used.
The `log_mf_h` is a `gen_event` handler module which can be installed in any `gen_event` process. It logs onto disk all events which are sent to an event manager. Each event is written as a binary which makes the logging very fast. However, a tool such as the `Report Browser (rb)` must be used in order to read the files. The events are written to multiple files. When all files have been used, the first one is re-used and overwritten. The directory location, the number of files, and the size of each file are configurable. The directory will include one file called `index`, and report files 1, 2, ....

Exports

`init(Dir, MaxBytes, MaxFiles)`
`init(Dir, MaxBytes, MaxFiles, Pred) -> Args`

Types:
- `Dir` = `string()`
- `MaxBytes` = `integer()`
- `MaxFiles` = `0 < integer() < 256`
- `Pred` = `fun(Event) -> boolean()`
- `Event` = `term()`
- `Args` = `args()`

Initiates the event handler. This function returns `Args`, which should be used in a call to `gen_event:add_handler(EventMgr, log_mf_h, Args)`.

`Dir` specifies which directory to use for the log files. `MaxBytes` specifies the size of each individual file. `MaxFiles` specifies how many files are used. `Pred` is a predicate function used to filter the events. If no predicate function is specified, all events are logged.

See Also

`gen_event(3), rb(3)`
This module provides an interface to a number of mathematical functions.

Exports

\[
\begin{align*}
\text{pi()} & \rightarrow \text{float()} \\
\text{sin}(X) & \\
\text{cos}(X) & \\
\text{tan}(X) & \\
\text{asin}(X) & \\
\text{acos}(X) & \\
\text{atan}(X) & \\
\text{atan2}(Y, X) & \\
\text{sinh}(X) & \\
\text{cosh}(X) & \\
\text{tanh}(X) & \\
\text{asinh}(X) & \\
\text{acosh}(X) & \\
\text{atanh}(X) & \\
\text{exp}(X) & \\
\text{log}(X) & \\
\text{log10}(X) & \\
\text{pow}(X, Y) & \\
\text{sqrt}(X) & \\
\text{erf}(X) & \rightarrow \text{float()} \\
\text{erf}(X) & \rightarrow \text{float}()
\end{align*}
\]

Types:
- \( X = Y = \text{number()} \)

A collection of math functions which return floats. Arguments are numbers.

\[
\begin{align*}
\text{erf}(X) & \rightarrow \text{float()} \\
\text{erf}(X) & \rightarrow \text{float}()
\end{align*}
\]

Types:
- \( X = \text{number()} \)

Returns the error function of \( X \), where

\[
\text{erf}(X) = \frac{2}{\sqrt{\pi}} \int_0^X e^{-t^2} dt.
\]
erfc(X) -> float()

Types:
- X = number()

erfc(X) returns 1.0 - erf(X), computed by methods that avoid cancellation for large X.

Bugs

As these are the C library, the bugs are the same.
ms_transform

Erlang Module

This module implements the parse_transform that makes calls to ets and dbg:fun2ms/1 translate into literal match specifications. It also implements the backend for the same functions when called from the erlang shell.

The translations from fun's to match_specs is accessed through the two “pseudo functions” ets:fun2ms/1 and dbg:fun2ms/1.

**Warning:**
To use the pseudo functions triggering the translation, one has to include the header file ms_transform.hrl in the source code. Failure to do so will possibly result in runtime errors rather than compile time, as the expression may be valid as a plain erlang program without translation.

**Warning:**
The fun has to be literally constructed inside the parameter list to the pseudo functions. The fun cannot be bound to a variable first and then passed to ets:fun2ms or dbg:fun2ms, i.e this will work: ets:fun2ms(fun(A) -> A end) but not this. F = fun(A) -> A end, ets:fun2ms(F). The later will result in a compile time error if the header is included, otherwise a runtime error. Even if the later construction would ever appear to work, it really doesn't, so don't ever use it.

Several restrictions apply to the fun that is being translated into a match_spec. To put it simple you cannot use anything in the fun that you cannot use in a match_spec. This means that, among others, the following restrictions apply to the fun itself:

- Functions written in erlang cannot be called, neither local functions, global functions or real fun's
- Everything that is written as a function call will be translated into a match_spec call to a builtin function, so that the call is_list(X) will be translated to {'is_list', '$1'} ('$1' is just an example, the numbering may vary). If one tries to call a function that is not a match_spec builtin, it will cause an error.
- Variables occurring in the head of the fun will be replaced by match_spec variables in the order of occurrence, so that the fragment fun({A,B,C}) will be replaced by {'$1', '$2', '$3'} etc. Every occurrence of such a variable later in the match_spec will be replaced by a match_spec variable in the same way, so that the fun fun({A,B}) when is_atom(A) -> B end will be translated into [[{'$1', '$2'}], [{'is_atom', '$1'}, ['$2']]].
Variables that are not appearing in the head are imported from the environment and made into match_spec const expressions. Example from the shell:

1> X = 25.
25
2> ets:fun2ms(fun({A,B}) when A > X -> B end).
[{{'$1','$2'},[['>','$1',{const,25}]],['$2']}]  

Matching with == cannot be used, neither in the head nor in the body. Example from the shell again:

1> ets:fun2ms(fun({A,[B|C]=D}) when A > X -> B end).
Error: fun with head matching ('=' in head) cannot be translated into match_spec
{error,transform_error}
2> ets:fun2ms(fun({A,[B|C]}) when A > X -> D = [B|C], D end).
Error: fun with body matching ('=' in body) is illegal as match_spec
{error,transform_error}

All variables are bound in the head and the match_spec syntax does not allow multiple bindings.

The special match_spec variables '$_' and '$*' are accessed through the pseudo functions object() (for '$_') and bindings() (for '$*'). As an example, one could translate the following ets:match_object/2 call to a ets:select call:

ets:match_object(Table, {'$1',test,'$2'}).  

...is the same as...

ets:select(Table, ets:fun2ms(fun({A,test,B}) -> object() end)).

(This was just an example, in this simple case the former expression is probably preferable in terms of readability). The ets:select/2 call will conceptually look like this in the resulting code:

ets:select(Table, [{'$1',test,'$2'},[],['$_']}).

Term constructions/literals are translated as much as is needed to get them into valid match_specs, so that tuples are made into match_spec tuple constructions (a one element tuple containing the tuple) and constant expressions are used when importing variables from the environment. Records are also translated into plain tuple constructions, calls to element etc. The guard test is_record/2 is translated into match_spec code using the three parameter version that's built into match_specs so that is_record(A,t) is translated into {is_record,'$1',t,5} given that the record size of record type t is 5. Records are of course still not accessible from the shell...

Language constructions like case, if, catch etc that are not present in match_specs are not allowed.

The old names for the guard type tests (list, integer, float etc) are not allowed. All guard tests must be written with the new names is_list, is_tuple, is_record etc.

If the header file ms_transform.hrl is not included, the fun won't be translated, which may result in a runtime error (depending on if the fun is valid in a pure erlang context). Be absolutely sure that the header is included when using ets and dbg:fun2ms/1 in compiled code.

If the pseudo function triggering the translation is ets:fun2ms/1, the fun's head must contain a single variable or a single tuple. If the pseudo function is dbg:fun2ms/1 the fun's head must contain a single variable or a single list.
The translation from fun's to match_spec's is done at compile time, so runtime performance is not affected by using these pseudo functions. The compile time might be somewhat longer though.

For more information about match_specs, please read about them in erts users guide.

Exports

parse_transform(Forms, Options) -> Forms

Types:
- Forms = Erlang abstract code format, see the erl_parse module description
- Options = Option list, required but not used

Implements the actual transformation at compile time. This function is called by the compiler to do the source code transformation if and when the ms_transform.hrl header file is included in your source code. See the ets and dbg:fun2ms/1 function manual pages for documentation on how to use this parse_transform, see the match_spec chapter in ERTS users guide for a description of match specifications.

transform_from_shell(Dialect, Clauses, BoundEnvironment) -> term()

Types:
- Dialect = ets | dbg
- Clauses = Erlang abstract form for a single fun
- BoundEnvironment = [{atom(), term()}, ...], list of variable bindings in the shell environment

Implements the actual transformation when the fun2ms functions are called from the shell. In this case the abstract form is for one single fun (parsed by the erlang shell), and all imported variables should be in the key-value list passed as BoundEnvironment. The result is a term, normalized, i.e. not in abstract format.

format_error(Errcode) -> ErrMessage

Types:
- Errcode = term()
- ErrMessage = string()

Takes an error code returned by one of the other functions in the module and creates a textual description of the error. Fairly uninteresting function actually.
orddict

Erlang Module

Orddict implements a Key - Value dictionary. An orddict is a representation of a dictionary, where a list of pairs is used to store the keys and values. The list is ordered after the keys.

This module provides exactly the same interface as the module dict but with a defined representation.
Sets are collections of elements with no duplicate elements. An ordset is a representation of a set, where an ordered list is used to store the elements of the set. An ordered list is more efficient than an unordered list. This module provides exactly the same interface as the module sets but with a defined representation.
pg

Erlang Module

This (experimental) module implements process groups. A process group is a group of processes that can be accessed by a common name. For example, a group named `foobar` can include a set of processes as members of this group and they can be located on different nodes.

When messages are sent to the named group, all members of the group receive the message. The messages are serialized. If the process `P1` sends the message `M1` to the group, and process `P2` simultaneously sends message `M2`, then all members of the group receive the two messages in the same order. If members of a group terminate, they are automatically removed from the group.

This module is not complete. The module is inspired by the ISIS system and the causal order protocol of the ISIS system should also be implemented. At the moment, all messages are serialized by sending them through a group master process.

Exports

```erlang
create(PgName)
    Creates an empty group named PgName on the current node.

create(PgName, Node)
    Creates an empty group on the node Node.

join(PgName, Pid)
    Joins the Pid Pid to the process group PgName.

send(PgName, Message)
    Sends the tuple `{pg_message, From, PgName, Message}` to all members of the process group.

esend(PgName, Message)
    Sends the tuple `{pg_message, From, PgName, Message}` to all members of the process group, except the current node.

members(PgName)
    Returns a list of the current members in the process group.
```
pool

Erlang Module

pool can be used to run a set of Erlang nodes as a pool of computational processors. It is organized as a master and a set of slave nodes and includes the following features:

- The slave nodes send regular reports to the master about their current load.
- Queries can be sent to the master to determine which node will have the least load.

The BIF `statistics(run_queue)` is used for estimating future loads. It returns the length of the queue of ready to run processes in the Erlang runtime system.

The slave nodes are started with the `slave` module. This effects tty IO, file IO, and code loading.

If the master node fails, the entire pool will exit.

Exports

```erlang
start(Name)
```

Starts a new pool. The file `.hosts.erlang` is read to find host names where the pool nodes can be started. The current working directory is searched first, then the home directory, and finally the root directory of the Erlang runtime system. The start-up procedure fails if the file is not found.

Name is sent to all pool nodes. This is used as the first part of the node name in the `alive/3` statements for the nodes.

The function `net_adm:host_file()` reads the file `.hosts.erlang` for host names. The slave nodes are started with `slave:start`. See `slave(3)`.

`start/1` is synchronous and all the nodes, as well as all the system servers, are running when it returns a value. Access rights must also be set so that all nodes in the pool have the authority to access each other.

```erlang
start(Name, Args)
```

This function is the same as `start/1`, except that the environment `Args` is passed to the pool nodes. See `slave(3)`.

```erlang
attach(Node)
```

This function ensures that a pool master is running and includes `Node` in the pool master's pool of nodes.

```erlang
stop()
```
Stops the pool and kills all the slave nodes.

\texttt{get\_nodes()}

Returns a list of the current member nodes of the pool.

\texttt{pspawn(Mod, Fun, Args)}

Spawns a process on the pool node which is expected to have the lowest future load.

\texttt{pspawn\_link(Mod, Fun, Args)}

Spawn links a process on the pool node which is expected to have the lowest future load.

\texttt{get\_node()}

Returns the node ID of the node with the expected lowest future load.

\texttt{new\_node(Host, Name)}

Starts a new node and attaches it to an already existing pool. If there is no existing pool, it starts a pool with two nodes, the current node and \texttt{Name}. This function can also be used as a convenient way of starting new nodes, even if the load distribution facilities of the pool are of no interest.

\section*{Files}

\$\texttt{HOME/.hosts.erlang}\ is used to pick hosts where nodes can be started. \$\texttt{HOME/erlang.slave.out.HOST}\ is used for all additional IO that may come from the slave nodes on standard IO. If the start-up procedure does not work, this file may indicate the reason.
**proc_lib**

Erlang Module

The *proc_lib* module is used to initialize some useful information when a process starts. The registered names, or the process identities, of the parent process, and the parent ancestors, are stored together with information about the function initially called in the process.

A crash report is generated if the process terminates with a reason other than normal or shutdown. shutdown is used to terminate an abnormal process in a controlled manner. A crash report contains the previously stored information such as ancestors and initial function, the termination reason, and information regarding other processes which terminate as a result of this process terminating.

The crash report is sent to the *error_logger*. An event handler has to be installed in the *error_logger* event manager in order to handle these reports. The crash report is tagged crash_report and the format/1 function should be called in order to format the report.

**Exports**

```
spawn(Module,Func,Args) -> Pid
spawn(Node,Module,Func,Args) -> Pid
```

Types:
- Module = atom()
- Func = atom()
- Args = [Arg]
- Arg = term()
- Node = atom()
- Pid = pid()

Spawns a new process and initializes it as described above. The process is spawned using the *spawn* BIF. The process can be spawned on another *Node*.

```
spawn_link(Module,Func,Args) -> Pid
spawn_link(Node,Module,Func,Args) -> Pid
```

Types:
- Module = atom()
- Func = atom()
- Args = [Arg]
- Arg = term()
- Node = atom()
Spawns a new process and initializes it as described above. The process is spawned using the spawn_link BIF. The process can be spawned on another Node.

\[
\text{spawn_opt(Module, Func, Args, Opts)} \rightarrow \text{Pid}
\]

**Types:**
- Module = atom()
- Func = atom()
- Args = [Arg]
- Arg = term()
- Opts = list()
- Pid = pid()

Spawns a new process and initializes it as described above. The process is spawned using the spawn_opt/4 BIF. The Opts argument is passed to spawn_opt/4.

\[
\text{start(Module, Func, Args)} \rightarrow \text{Ret}
\]

\[
\text{start(Module, Func, Args, Time)} \rightarrow \text{Ret}
\]

\[
\text{start(Module, Func, Args, Time, SpawnOpts)} \rightarrow \text{Ret}
\]

\[
\text{start_link(Module, Func, Args)} \rightarrow \text{Ret}
\]

\[
\text{start_link(Module, Func, Args, Time)} \rightarrow \text{Ret}
\]

\[
\text{start_link(Module, Func, Args, Time, SpawnOpts)} \rightarrow \text{Ret}
\]

**Types:**
- Module = atom()
- Func = atom()
- Args = [Arg]
- Arg = term()
- Time = integer \( \geq 0 \) \| infinity
- SpawnOpts = list()
- Ret = term() \| {error, Reason}

Starts a new process synchronously. Spawns the process using proc_lib:spawn/3 or proc_lib:spawn_link/3, and waits for the process to start. When the process has started, it must call proc_lib:init_ack(Parent, Ret) or proc_lib:init_ack(Ret), where Parent is the process that evaluates start. At this time, Ret is returned from start.

If the start_link function is used and the process crashes before proc_lib:init_ack is called, \{error, Reason\} is returned if the calling process traps exits.

If Time is specified as an integer, this function waits for Time milliseconds for the process to start (proc_lib:init_ack). If it has not started within this time, \{error, timeout\} is returned, and the process is killed.

The SpawnOpts argument, if given, will be passed as the last argument to the spawn_opt/4 BIF. Refer to the erlang module for information about the spawn_opt options.

\[
\text{init_ack(Parent, Ret)} \rightarrow \text{void()}
\]

\[
\text{init_ack(Ret)} \rightarrow \text{void()}
\]
Types:
- Parent = pid()
- Ret = term()

This function is used by a process that has been started by a `proc_lib:start` function. It tells Parent that the process has initialized itself, has started, or has failed to initialize itself. The `init_ack/1` function uses the parent value previously stored by the `proc_lib:start` function. If the `init_ack` function is not called (e.g. if the init function crashes) and `proc_lib:start/3` is used, that function never returns and the parent hangs forever. This can be avoided by using a time out in the call to `start`, or by using `start_link`.

The following example illustrates how this function and `proc_lib:start_link` are used.

```erlang
-module(my_proc).
-export([start_link/0]).
start_link() ->
    proc_lib:start_link(my_proc, init, [self()]).
init(Parent) ->
    case do_initialization() of
        ok ->
            proc_lib:init_ack(Parent, {ok, self()});
        {error, Reason} ->
            exit(Reason)
    end,
    loop().
loop() ->
    receive ....
    end.
format(CrashReport) -> string()
```

Types:
- CrashReport = void()

Formats a previously generated crash report. The formatted report is returned as a string.

```erlang
initial_call(PidOrPinfo) -> {Module,Function,Args} | false
```

Types:
- PidOrPinfo = pid() | {X,Y,Z} | ProcInfo
- X = Y = Z = int()
- ProcInfo = [void()]
- Module = atom()
- Function = atom()
- Args = [term()]

Extracts the initial call of a process that was spawned using the spawn functions described above. `PidOrPinfo` can either be a Pid, an integer tuple (from which a pid can be created), or the process information of a process (fetched through a `erlang:process_info/1` function call).

```erlang
translate_initial_call(PidOrPinfo) -> {Module,Function,Arity}
```

...
Types:
- PidOrPinfo = pid() | {X,Y,Z} | ProcInfo
- X = Y = Z = int()
- ProcInfo = [void()]
- Module = atom()
- Function = atom()
- Arity = int()

Extracts the initial call of a process which was spawned using the spawn functions described above. If the initial call is to one of the system defined behaviours such as gen_server or gen_event, it is translated to more useful information. If a gen_server is spawned, the returned Module is the name of the callback module and Function is init (the function that initiates the new server).

A supervisor and a supervisor_bridge are also gen_server processes. In order to return information that this process is a supervisor and the name of the callback module, Module is supervisor and Function is the name of the supervisor callback module. Arity is 1 since the init/1 function is called initially in the callback module.

By default, [proc_lib, init_p, 5] is returned if no information about the initial call can be found. It is assumed that the caller knows that the process has been spawned with the proc_lib module.

PidOrPinfo can either be a Pid, an integer tuple (from which a pid can be created), or the process information of a process (fetched through a erlang:process_info/1 function call).

This function is used by the c:I/0 and c:regs/0 functions in order to present process information.

error_logger(3)
proplists

Erlang Module

Property lists are ordinary lists containing entries in the form of either tuples, whose first elements are keys used for lookup and insertion, or atoms, which work as shorthand for tuples \{Atom, true\}. (Other terms are allowed in the lists, but are ignored by this module.) If there is more than one entry in a list for a certain key, the first occurrence normally overrides any later (irrespective of the arity of the tuples).

Property lists are useful for representing inherited properties, such as options passed to a function where a user may specify options overriding the default settings, object properties, annotations, etc.

Exports

append_values(Key, List) -> List

Types:
- Key = term()
- List = [term()]

Similar to get_all_values/2, but each value is wrapped in a list unless it is already itself a list, and the resulting list of lists is concatenated. This is often useful for "incremental" options; e.g., append_values(a, [[a, [1,2]], {b, 0}, {a, 3}, {c, -1}, {a, [4]]]) will return the list [1,2,3,4].

compact(List) -> List

Types:
- List = [term()]

Minimizes the representation of all entries in the list. This is equivalent to [property(P) || P <- List].

See also: property/1, unfold/1.

delete(Key, List) -> List

Types:
- Key = term()
- List = [term()]

Deletes all entries associated with Key from List.

expand(Expansions, List) -> List

Types:
Key = term()
Expansions = [{Property,[term()]]}
Property = atom() | tuple()

Expands particular properties to corresponding sets of properties (or other terms). For each pair \{Property, Expansion\} in Expansions, if E is the first entry in List with the same key as Property, and E and Property have equivalent normal forms, then E is replaced with the terms in Expansion, and any following entries with the same key are deleted from List.

For example, the following expressions all return [fie, bar, baz, fum]:

```prolog
expand([foo, [bar, baz]], [fie, foo, fum])
expand([[[foo, true], [bar, baz]], [fie, foo, fum])
expand([[[foo, false], [bar, baz]], [fie, {foo, false}, fum])
```

However, no expansion is done in the following call:

```prolog
expand([[[foo, true], [bar, baz]], [{foo, false}, fie, foo, fum])
```

because \{foo, false\} shadows foo.

Note that if the original property term is to be preserved in the result when expanded, it must be included in the expansion list. The inserted terms are not expanded recursively. If Expansions contains more than one property with the same key, only the first occurrence is used.

See also: normalize/2.

get_all_values(Key, List) -> [term()]

Types:
- Key = term()
- List = [term()]

Similar to get_value/2, but returns the list of values for all entries \{Key, Value\} in List. If no such entry exists, the result is the empty list.

See also: get_value/2.

get_bool(Key, List) -> bool()

Types:
- Key = term()
- List = [term()]

Returns the value of a boolean key/value option. If lookup(Key, List) would yield \{Key, true\}, this function returns true; otherwise false is returned.

See also: get_value/2, lookup/2.

get_keys(List) -> [term()]

Types:
- List = [term()]
get_value(Key, List) -> term()

Types:
- Key = term()
- List = [term()]

Equivalent to get_value(Key, List, undefined).

get_value(Key, List, Default) -> term()

Types:
- Key = term()
- Default = term()
- List = [term()]

Returns the value of a simple key/value property in List. If lookup(Key, List) would yield {Key, Value}, this function returns the corresponding Value, otherwise Default is returned.

See also: get_all_values/2, get_bool/2, get_value/1, lookup/2.

is_defined(Key, List) -> bool()

Types:
- Key = term()
- List = [term()]

Returns true if List contains at least one entry associated with Key, otherwise false is returned.

lookup(Key, List) -> none | tuple()

Types:
- Key = term()
- List = [term()]

Returns the first entry associated with Key in List, if one exists, otherwise returns none. For an atom A in the list, the tuple {A, true} is the entry associated with A.

See also: get_bool/2, get_value/2, lookup_all/2.

lookup_all(Key, List) -> [tuple()]

Types:
- Key = term()
- List = [term()]

Returns the list of all entries associated with Key in List. If no such entry exists, the result is the empty list.

See also: lookup/2.

normalize(List, Stages) -> List

Types:
• List = [term()]
• Stages = [Operation]
• Operation = {aliases, Aliases} | {negations, Negations} | {expand, Expansions}
• Aliases = [{Key, Key}]
• Negations = [{Key, Key}]
• Key = term()
• Expansions = [{Property, [term()]},
• Property = atom() | tuple()

Passes List through a sequence of substitution/expansion stages. For an aliases operation, the function substitute_aliases/2 is applied using the given list of aliases; for a negations operation, substitute_negations/2 is applied using the given negation list; for an expand operation, the function expand/2 is applied using the given list of expansions. The final result is automatically compacted (cf. compact/1).

Typically you want to substitute negations first, then aliases, then perform one or more expansions (sometimes you want to pre-expand particular entries before doing the main expansion). You might want to substitute negations and/or aliases repeatedly, to allow such forms in the right-hand side of aliases and expansion lists.

See also: compact/1, expand/2, substitute_aliases/2, substitute_negations/2.

property( Property ) -> Property
Types:
• Property = atom() | tuple()  

Creates a normal form (minimal) representation of a property. If Property is {Key, true} where Key is an atom, this returns Key, otherwise the whole term Property is returned.

See also: property/2.

property(Key, Value) -> Property
Types:
• Key = term()
• Value = term()
• Property = atom() | tuple()  

Creates a normal form (minimal) representation of a simple key/value property. Returns Key if Value is true and Key is an atom, otherwise a tuple {Key, Value} is returned.

See also: property/1.

substitute_aliases(Aliases, List) -> List
Types:
• Aliases = [{Key, Key}]
• Key = term()
• List = [term()]
Substitutes keys of properties. For each entry in List, if it is associated with some key \( K_1 \) such that \( \{ K_1, K_2 \} \) occurs in Aliases, the key of the entry is changed to \( K_2 \). If the same \( K_1 \) occurs more than once in Aliases, only the first occurrence is used.

Example: `substitute_aliases([[color, colour]], L)` will replace all tuples \( \{color, ...\} \) in \( L \) with \( \{colour, ...\} \), and all atoms color with colour.

See also: `normalize/2, substitute_negations/2`.

### substitute_negations(Negations, List) \rightarrow List

**Types:**

- \( \text{Negations} = \{\text{Key, Key}\} \)
- \( \text{Key} = \text{term()} \)
- \( \text{List} = \{\text{term()}\} \)

Substitutes keys of boolean-valued properties and simultaneously negates their values. For each entry in List, if it is associated with some key \( K_1 \) such that \( \{ K_1, K_2 \} \) occurs in Negations, then if the entry was \( \{ K_1, \text{true} \} \) it will be replaced with \( \{ K_2, \text{false} \} \), otherwise it will be replaced with \( \{ K_2, \text{true} \} \), thus changing the name of the option and simultaneously negating the value given by `get_bool(List)`. If the same \( K_1 \) occurs more than once in Negations, only the first occurrence is used.

Example: `substitute_negations([[no_foo, foo]], L)` will replace any atom `no_foo` or tuple `\{no_foo, true\}` in \( L \) with `foo, false`, and any other tuple `\{no_foo, ...\}` with `\{foo, true\}`.

See also: `get_bool/2, normalize/2, substitute_aliases/2`.

### unfold(List) \rightarrow List

**Types:**

- \( \text{List} = \{\text{term()}\} \)

Unfolds all occurrences of atoms in List to tuples `\{Atom, true\}`.
queue
Erlang Module

This module implements FIFO queues in an efficient manner.

Exports

new() -> Queue
Types:
  • Queue = queue()
Returns an empty queue.

in(Item, Q1) -> Q2
Types:
  • Item = term()
  • Q1 = Q2 = queue()
Inserts Item into the queue Q1. Returns a new queue Q2.

out(Q) -> Result
Types:
  • Result = [{value, Item}, Q1] | {empty, Q1}
  • Q = Q1 = queue()
Removes the oldest element from the queue Q. Returns the tuple [{value, Item}, Q1], where Item is the element removed and Q1 is an identifier for the new queue. If Q is empty, the tuple {empty, Q} is returned.

to_list(Q) -> list()
Types:
  • Q = queue()
Returns a list of the elements in the queue, with the oldest element first.

The current algorithm is a modification of the version attributed to Richard A O'Keefe in the standard Prolog library.

Every time a random number is requested, a state is used to calculate it, and a new state produced. The state can either be implicit (kept in the process dictionary) or be an explicit argument and return value. In this implementation, the state (the type \texttt{ran()}) consists of a tuple of three integers.

Exports

\texttt{seed() -> ran()}

Seeds random number generation with default (fixed) values in the process dictionary, and returns the old state.

\texttt{seed(A1, A2, A3) -> ran()}

Types:
- \texttt{A1 = A2 = A3 = int()}

Seeds random number generation with integer values in the process dictionary, and returns the old state.

\texttt{seed0() -> ran()}

Returns the default state.

\texttt{uniform() -> float()}

Returns a random float uniformly distributed between 0.0 and 1.0, updating the state in the process dictionary.

\texttt{uniform(N) -> int()}

Types:
- \texttt{N = int()}

Given an integer \texttt{N >= 1}, \texttt{uniform/1} returns a random integer uniformly distributed between 1 and \texttt{N}, updating the state in the process dictionary.
uniform_s(State0) -> {float(), State1}

Types:
- State0 = State1 = ran()

Given a state, uniform_s/1 returns a random float uniformly distributed between 0.0 and 1.0, and a new state.

uniform_s(N, State0) -> {int(), State1}

Types:
- N = int()
- State0 = State1 = ran()

Given an integer \( N \geq 1 \) and a state, uniform_s/2 returns a random integer uniformly distributed between 1 and \( N \), and a new state.

**Note**

Some of the functions use the process dictionary variable `random_seed` to remember the current seed.

If a process calls `uniform/0` or `uniform/1` without setting a seed first, `seed/0` is called automatically.
Erlang Module

This module contains functions for regular expression matching and substitution.

Exports

match(String, RegExp) -> MatchRes

Types:
- String = RegExp = string()
- MatchRes = {match,Start,Length} | nomatch | {error,errordesc()}
- Start = Length = integer()

Finds the first, longest match of the regular expression RegExp in String. This function searches for the longest possible match and returns the first one found if there are several expressions of the same length. It returns as follows:

{match,Start,Length} if the match succeeded. Start is the starting position of the match, and Length is the length of the matching string.

nomatch if there were no matching characters.

{error,Error} if there was an error in RegExp.

first_match(String, RegExp) -> MatchRes

Types:
- String = RegExp = string()
- MatchRes = {match,Start,Length} | nomatch | {error,errordesc()}
- Start = Length = integer()

Finds the first match of the regular expression RegExp in String. This call is usually faster than match and it is also a useful way to ascertain that a match exists. It returns as follows:

{match,Start,Length} if the match succeeded. Start is the starting position of the match and Length is the length of the matching string.

nomatch if there were no matching characters.

{error,Error} if there was an error in RegExp.

matches(String, RegExp) -> MatchRes

Types:
- String = RegExp = string()
• MatchRes = (match, Matches) | {error, errordesc()}
• Matches = list()
Finds all non-overlapping matches of the expression RegExp in String. It returns as follows:

{match, Matches} if the regular expression was correct. The list will be empty if there was no match. Each element in the list looks like {Start, Length}, where Start is the starting position of the match, and Length is the length of the matching string.

{error, Error} if there was an error in RegExp.

sub(String, RegExp, New) -> SubRes
Types:
• String = RegExp = New = string()
• SubRes = {ok, NewString, RepCount} | {error, errordesc()}
• RepCount = integer()
Substitutes the first occurrence of a substring matching RegExp in String with the string New. A \& in the string New is replaced by the matched substring of String. \& puts a literal \& into the replacement string. It returns as follows:

{ok, NewString, RepCount} if RegExp is correct. RepCount is the number of replacements which have been made (this will be either 0 or 1).

{error, Error} if there is an error in RegExp.

gsub(String, RegExp, New) -> SubRes
Types:
• String = RegExp = New = string()
• SubRes = {ok, NewString, RepCount} | {error, errordesc()}
• RepCount = integer()
The same as sub, except that all non-overlapping occurrences of a substring matching RegExp in String are replaced by the string New. It returns:

{ok, NewString, RepCount} if RegExp is correct. RepCount is the number of replacements which have been made.

{error, Error} if there is an error in RegExp.

split(String, RegExp) -> SplitRes
Types:
• String = RegExp = string()
• SubRes = {ok, FieldList} | {error, errordesc()}
• FieldList = [string()]
String is split into fields (sub-strings) by the regular expression RegExp. If the separator expression is " " (a single space), then the fields are separated by blanks and/or tabs and leading and trailing blanks and tabs are discarded. For all other values of the separator, leading and trailing blanks and tabs are not discarded. It returns:
\{ok, FieldList\} to indicate that the string has been split up into the fields of FieldList.
\{error, Error\} if there is an error in RegExp.

\texttt{sh_to_awk(ShRegExp) -> AwkRegExp}

Types:
\begin{itemize}
  \item ShRegExp AwkRegExp = string()
  \item SubRes = \{ok, NewString, RepCount\} | \{error, errordesc()\}
  \item RepCount = integer()
\end{itemize}

Converts the sh type regular expression ShRegExp into a full AWK regular expression. Returns the converted regular expression string. sh expressions are used in the shell for matching file names and have the following special characters:

* matches any string including the null string.
? matches any single character.
[... ] matches any of the enclosed characters. Character ranges are specified by a pair of characters separated by a -. If the first character after [ is a !, then any character not enclosed is matched.

It may sometimes be more practical to use sh type expansions as they are simpler and easier to use, even though they are not as powerful.

\texttt{parse(RegExp) -> ParseRes}

Types:
\begin{itemize}
  \item RegExp = string()
  \item ParseRes = \{ok, RE\} | \{error, errordesc()\}
\end{itemize}

Parses the regular expression RegExp and builds the internal representation used in the other regular expression functions. Such representations can be used in all of the other functions instead of a regular expression string. This is more efficient when the same regular expression is used in many strings. It returns:

\{ok, RE\} \textbf{if RegExp is correct and RE is the internal representation.}
\{error, Error\} \textbf{if there is an error in RegExpString.}

\texttt{format_error(ErrorDescriptor) -> string()}

Types:
\begin{itemize}
  \item ErrorDescriptor = errordesc()
\end{itemize}

Returns a string which describes the error ErrorDescriptor returned when there is an error in a regular expression.
Regular Expressions

The regular expressions allowed here is a subset of the set found in `egrep` and in the `AWK` programming language, as defined in the book, *The AWK Programming Language*, by A. V. Aho, B. W. Kernighan, P. J. Weinberger. They are composed of the following characters:

- `c` matches the non-metacharacter `c`.
- \`c` matches the escape sequence or literal character `c`.
- . matches any character.
- ^ matches the beginning of a string.
- $ matches the end of a string.
- [abc...] character class, which matches any of the characters abc... Character ranges are specified by a pair of characters separated by a `-`.
- [^-abc...] negated character class, which matches any character except abc.....
- r1 | r2 alternation. It matches either r1 or r2.
- r1r2 concatenation. It matches r1 and then r2.
- r+ matches one or more rs.
- r* matches zero or more rs.
- r? matches zero or one rs.
- (r) grouping. It matches r.

The escape sequences allowed are the same as for Erlang strings:

- \b backspace
- \f form feed
- \n newline (line feed)
- \r carriage return
- \t tab
- \e escape
- \v vertical tab
- \s space
- \d delete
- \ddd the octal value ddd
- \c any other character literally, for example \ for backslash, " for ")

To make these functions easier to use, in combination with the function `io:get_line` which terminates the input line with a new line, the $ characters also matches a string ending with "...\n". The following examples define Erlang data types:

<table>
<thead>
<tr>
<th>Atoms</th>
<th><code>[a-z][0-9a-zA-Z]*</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>Variables</td>
<td><code>[A-Z][0-9a-zA-Z]*</code></td>
</tr>
<tr>
<td>Floats</td>
<td>`(+</td>
</tr>
</tbody>
</table>
Regular expressions are written as Erlang strings when used with the functions in this module. This means that any \ or " characters in a regular expression string must be written with \ as they are also escape characters for the string. For example, the regular expression string for Erlang floats is:

```
"(\+|-)?[0-9]+\.[0-9]+([Ee](\+|-)?[0-9]+)?"
```

It is not really necessary to have the escape sequences as part of the regular expression syntax as they can always be generated directly in the string. They are included for completeness and can also be useful when generating regular expressions, or when they are entered other than with Erlang strings.
sets

Erlang Module

Sets are collections of elements with no duplicate elements. The representation of a set is not defined.

Exports

new() -> Set

Types:
• Set = set()
Returns a new empty ordered set.

is_set(Set) -> bool()

Types:
• Set = term()
Returns true if Set is an ordered set of elements, otherwise false.

size(Set) -> int()

Types:
• Set = term()
Returns the number of elements in Set.

to_list(Set) -> List

Types:
• Set = set()
• List = [term()]
Returns the elements of Set as a list.

from_list(List) -> Set

Types:
• List = [term()]
• Set = set()
Returns an ordered set of the elements in List.

is_element(Element, Set) -> bool()
Sets STDLIB Reference Manual

Types:
- \( \text{Element} = \text{term}() \)
- \( \text{Set} = \text{set}() \)

Returns \( \text{true} \) if \( \text{Element} \) is an element of \( \text{Set} \), otherwise \( \text{false} \).

**add_element(Element, Set1) \rightarrow Set2**

Types:
- \( \text{Element} = \text{term}() \)
- \( \text{Set1} = \text{Set2} = \text{set}() \)

Returns a new ordered set formed from \( \text{Set1} \) with \( \text{Element} \) inserted.

**del_element(Element, Set1) \rightarrow Set2**

Types:
- \( \text{Element} = \text{term}() \)
- \( \text{Set1} = \text{Set2} = \text{set}() \)

Returns \( \text{Set1} \), but with \( \text{Element} \) removed.

**union(Set1, Set2) \rightarrow Set3**

Types:
- \( \text{Set1} = \text{Set2} = \text{Set3} = \text{set}() \)

Returns the merged (union) set of \( \text{Set1} \) and \( \text{Set2} \).

**union(SetList) \rightarrow Set**

Types:
- \( \text{SetList} = [\text{set}()] \)
- \( \text{Set} = \text{set}() \)

Returns the merged (union) set of the list of sets.

**intersection(Set1, Set2) \rightarrow Set3**

Types:
- \( \text{Set1} = \text{Set2} = \text{Set3} = \text{set}() \)

Returns the intersection of \( \text{Set1} \) and \( \text{Set2} \).

**intersection(SetList) \rightarrow Set**

Types:
- \( \text{SetList} = [\text{set}()] \)
- \( \text{Set} = \text{set}() \)

Returns the intersection of the non-empty list of sets.

**subtract(Set1, Set2) \rightarrow Set3**

Types:
- \( \text{Set1} = \text{Set2} = \text{Set3} = \text{set}() \)
Returns only the elements of Set1 which are not also elements of Set2.

\texttt{is\_subset(Set1, Set2)} \rightarrow \texttt{bool()}

Types:
- \texttt{Set1 = Set2 = set()}

Returns true when every element of Set1 is also a member of Set2, otherwise false.

\texttt{fold(Function, Acc0, Set)} \rightarrow \texttt{Acc1}

Types:
- \texttt{Function = fun (E, AccIn) \rightarrow AccOut}
- \texttt{Acc0 = Acc1 = AccIn = AccOut = term()}
- \texttt{Set = set()}

Fold Function over every element in Set returning the final value of the accumulator.

\texttt{filter(Pred, Set1)} \rightarrow \texttt{Set2}

Types:
- \texttt{Pred = fun (E) \rightarrow bool()}
- \texttt{Set1 = Set2 = set()}

Filter elements in Set1 with boolean function Fun.
The module `shell` implements an Erlang shell. The shell is a user interface program for entering expression sequences. The expressions are evaluated and a value is returned. A history mechanism saves previous commands and their values, which can then be incorporated in later commands. How many commands and results to save can be determined by the user, either interactively, by calling `shell:history/1` and `shell:results/1`, or by setting the application configuration parameters `shell_history_length` and `shell_saved_results` for the application `stdlib`.

Variable bindings, and local process dictionary changes which are generated in user expressions, are preserved and the variables can be used in later commands to access their values. The bindings can also be forgotten so the variables can be re-used.

The special shell commands all have the syntax of (local) function calls. They are evaluated as normal function calls and many commands can be used in one expression sequence.

If a command (local function call) is not recognized by the shell, an attempt is first made to find the function in the module `user_default`, where customized local commands can be placed. If found, then the function is evaluated. Otherwise, an attempt is made to evaluate the function in the module `shell_default`. The module `user_default` must be explicitly loaded.

The shell also permits the user to start multiple concurrent jobs. A job can be regarded as a set of processes which can communicate with the shell.

The shell runs in two modes:

- **Normal mode**, in which commands can be edited and expressions evaluated
- **Job Control Mode JCL**, in which jobs can be started, killed, detached and connected.

Only the currently connected job can ‘talk’ to the shell.
Shell Commands

b() Prints the current variable bindings.

f() Removes all variable bindings.
f(X) Removes the binding of variable X.
h() Prints the history list.

history(N) Sets the number of previous commands to keep in the history list to N. The previous number is returned. The default number is 20.

results(N) Sets the number of results from previous commands to keep in the history list to N. The previous number is returned. The default number is 20.
e(N) Repeats the command N, if N is positive. If it is negative, the Nth previous command is repeated (i.e., e(-1) repeats the previous command).
v(N) Uses the return value of the command N in the current command.
help() Evaluates shell_default:help().
c(File) Evaluates shell_default:c(File). This compiles and loads code in File and purges old versions of code, if necessary. Assumes that the file and module names are the same.

Example

The following example is a long dialogue with the shell. Commands starting with > are inputs to the shell. All other lines are output from the shell. All commands in this example are explained at the end of the dialogue.

strider 1> erl
Erlang (BEAM) emulator version 4.9

Eshell V4.9 (abort with ^G)
1> Str = "abcd".
"abcd"
2> L = length(Str).
4
3> Descriptor = [{L, list_to_atom(Str)}].
{4,abcd}
4> L.
4
5> b().
Descriptor = {4,abcd}
L = 4
Str = "abcd"
ok
6> f(L).
ok
7> b().
Descriptor = {4,abcd}
Str = "abcd"
ok
8> f(L).
ok
9> \{L, _\} = Descriptor.
   \{4,abcd\}
10> {L}.
   4
11> \{P, Q, R\} = Descriptor.
** exited: \{\{badmatch,\{4,abcd\}\},\{erl_eval,expr,3\}\} **
12> P.
** exited: \{\{unbound,'P'\},\{erl_eval,expr,3\}\} **
13> Descriptor.
   \{4,abcd\}
14> \{P, Q\} = Descriptor.
   \{4,abcd\}
15> P.
   4
16> f().
ok
17> put(aa, hello).
   undefined
18> get(aa).
   hello
19> Y = test1:demo(1).
   11
20> get().
   [{aa,worked}]
21> put(aa, hello).
   worked
22> Z = test1:demo(2).
** exited: \{\{badmatch,1\},\{test1,demo,\[2\]\}\} **

=ERROR REPORT==== 24-Jan-1997::07:48:46 ===
!!! Error in process <0.22.0> with exit value: \{\{badmatch,1\},\{test1,demo,\[2\]\}\} 
23> Z.
** exited: \{\{unbound,'Z'\},\{erl_eval,expr,3\}\} **
24> get(aa).
   hello
25> erase(), put(aa, hello).
   undefined
26> spawn(test1, demo, \[1\]).
   <0.25.0>
27> get(aa).
   hello
28> io:format("hello hello\n").
   hello hello
ok
29> e(28).
   hello hello
ok
30> v(28).
   ok
31> test1:loop(0).
Hello Number: 0
Hello Number: 1
Hello Number: 2
Hello Number: 3

User switch command
  --i
  --c

Hello Number: 3374
Hello Number: 3375
Hello Number: 3376
Hello Number: 3377
Hello Number: 3378
** exited: killed **
32> halt()
strider 2>

Comments

Command 1 sets the variable Str to the string "abcd".
Command 2 sets L to the length of the string evaluating the BIF atom:tolist.
Command 3 builds the tuple Descriptor.
Command 4 prints the value of the variable L.
Command 5 evaluates the internal shell command b(), which is an abbreviation of "bindings". This prints the current shell variables and their bindings. The ok at the end is the return value of the b() function.
Command 6 f(L) evaluates the internal shell command f(L) (abbreviation of "forget"). The value of the variable L is removed.
Command 7 prints the new bindings.
Command 8 shows that the value of L has disappeared from the bindings.
Command 9 performs a pattern matching operation on Descriptor, binding a new value to L.
Command 10 prints the current value of L.
Command 11 tries to match {P, Q, R} against Descriptor which is {4, abc}. The match fails and none of the new variables become bound. The printout starting with "** exited:" is not the value of the expression (the expression had no value because its evaluation failed), but rather a warning printed by the system to inform the user that an error has occurred. The values of the other variables (L, Str, etc.) are unchanged.
Commands 12 and 13 show that P is unbound because the previous command failed, and that Descriptor has not changed.
Commands 14 and 15 show a correct match where P and Q are bound.
Command 16 clears all bindings.
The next few commands assume that test1:demo(X) is defined in the following way:
demo(X) ->
    put(aa, worked),
    X = 1,
    X + 10.

Commands 17 and 18 set and inspect the value of the item aa in the process dictionary. Command 19 evaluates test1:demo(1). The evaluation succeeds and the changes made in the process dictionary become visible to the shell. The new value of the dictionary item aa can be seen in command 20.

Commands 21 and 22 change the value of the dictionary item aa to hello and call test1:demo(2). Evaluation fails and the changes made to the dictionary in test1:demo(2), before the error occurred, are discarded.

Commands 23 and 24 show that z was not bound and that the dictionary item aa has retained its original value.

Commands 25, 26 and 27 show the effect of evaluating test1:demo(1) in the background. In this case, the expression is evaluated in a newly spawned process. Any changes made in the process dictionary are local to the newly spawned process and therefore not visible to the shell.

Commands 28, 29 and 30 use the history facilities of the shell. Command 29 is e(28). This re-evaluates command 28. Command 30 is v(28). This uses the value (result) of command 28. In the cases of a pure function (a function with no side effects), the result is the same. For a function with side effects, the result can be different.

For the next command, it is assumed that test1:loop(N) is defined in the following way:

    loop(N) ->
        io:format("Hello Number: ~w~n", [N]),
        loop(N+1).

Command 31 evaluates test1:loop(0), which puts the system into an infinite loop. At this point the user types Control G, which suspends output from the current process, which is stuck in a loop, and activates JCL mode. In JCL mode the user can start and stop jobs.

In this particular case, the i command ("interrupt") is used to terminate the looping program, and the c command is used to connect to the shell again. Since the process was running in the background before we killed it, there will be more printouts before the "** exited: killed **" message is shown.

The halt() command exits the Erlang runtime system.
JCL Mode

When the shell starts, it starts a single evaluator process. This process, together with any local processes which it spawns, is referred to as a job. Only the current job, which is said to be connected, can perform operations with standard IO. All other jobs, which are said to be detached, are blocked if they attempt to use standard IO.

All jobs which do not use standard IO run in the normal way.

\( ^{\text{G}} \) (Control G) detaches the current job and JCL mode is activated. The JCL mode prompt is "--->". If "?" is entered at the prompt, the following help message is displayed:

```
---> ?
c [nn] - connect to job
i [nn] - interrupt job
k [nn] - kill job
j - list all jobs
s - start local shell
r [node] - start remote shell
q - quit Erlang
? | h - this message
```

The JCL commands have the following meaning:

c [nn] Connects to job number <nn> or the current job. The standard shell is resumed. Operations which use standard IO by the current job will be interleaved with user inputs to the shell.

i [nn] Stops the current evaluator process for job number nn or the current job, but does not kill the shell process. Accordingly, any variable bindings and the process dictionary will be preserved and the job can be connected again. This command can be used to interrupt an endless loop.

k [nn] Kills job number nn or the current job. All spawned processes in the job are killed, provided they have not evaluated the group_leader/1 BIF and are located on the local machine. Processes spawned on remote nodes will not be killed.

j Lists all jobs. A list of all known jobs is printed. The current job name is prefixed with "."

s Starts a new job. This will be assigned the new index [nn] which can be used in references.

r [node] Starts a remote job on node. This is used in distributed Erlang to allow a shell running on one node to control a number of applications running on a network of nodes.

q Quits Erlang.

? Displays this message.
Exports

history(N) -> integer()

Types:
  * N = integer()

Sets the number of previous commands to keep in the history list to \( N \). The previous number is returned. The default number is 20.

results(N) -> integer()

Types:
  * N = integer()

Sets the number of results from previous commands to keep in the history list to \( N \). The previous number is returned. The default number is 20.
shell_default

Erlang Module

The functions in shell_default are called when no module name is given in a shell command. Consider the following shell dialogue:

1 > lists:reverse("abc").
   "cba"
2 > c(foo).
   ok, foo

In command one, the module lists is called. In command two, no module name is specified. The shell searches the modules user_default followed by shell_default for the function foo/1.

shell_default is intended for "system wide" customizations to the shell. user_default is intended for "local" or individual user customizations.

Hint

To add your own commands to the shell, create a module called user_default and add the commands you want. Then add the following line as the first line in your .erlang file in your home directory.

code:loadabs("$PATH/user_default").

$PATH is the directory where your user_default module can be found.
This module provides functions for starting Erlang slave nodes. All slave nodes which are started by a master will terminate automatically when the master terminates. All TTY output produced at the slave will be sent back to the master node. File I/O is done via the master.

Slave nodes on other hosts than the current one are started with the program `rsh`. The user must be allowed to `rsh` to the remote hosts without being prompted for a password. This can be arranged in a number of ways (refer to the `rsh` documentation for details). A slave node started on the same host as the master inherits certain environment values from the master, such as the current directory and the environment variables. For what can be assumed about the environment when a slave is started on another host, read the documentation for the `rsh` program.

An alternative to the `rsh` program can be specified on the command line to `erl` as follows: `-rsh Program`.

The slave node should use the same file system at the master. At least, Erlang/OTP should be installed in the same place on both computers and the same version of Erlang should be used.

Currently, a node running on Windows NT can only start slave nodes on the host on which it is running.

The master node must be alive.

**Exports**

`start(Host)`

Starts a slave node on the host `Host`. Host names need not necessarily be specified as fully qualified names; short names can also be used. This is the same condition that applies to names of distributed Erlang nodes. The name of the started node will be the same as the node which executes the call, with the exception of the host name part of the node name.

Return value: see `start/3`.

`start_link(Host)`

Starts a slave node on the host `Host` in the same way as the `start/1`, except that the slave node is linked to the currently executing process. If the process terminates, the slave node also terminates.

Return value: see `start/3`.

`start(Host, Name)`
Starts a slave node on the host Host with the name Name@Host.

Return value: see start/3.

\begin{verbatim}
start_link(Host, Name) 
Starts a slave node on the host Host in the same way as start/2, except that the slave
node is linked to the currently executing process. If that process terminates, the slave
node also terminates.
Return value: see start/3.
\end{verbatim}

\begin{verbatim}
start(Host, Name, Args) -> {ok, Node} | {error, ErrorInfo}
Starts a slave node with the name Name@Host on Host and passes the argument string
Args to the new node.
The slave node resets its user process so that all terminal I/O which is produced at the
slave is automatically relayed to the master. Also, the file process will be relayed to the
master.
The Args argument can be used for a variety of purposes. See erl(1). For example, the
following command line arguments can be passed to the slave:

- to set some environment variable on the slave
- to run some specific program on the slave
- to set some specific code path on the slave node.

As an example, suppose that we want to start a slave node at host H with the node name
Name@H, and we also want the slave node to have the following properties:

- directory Dir should be added to the code path;
- the Mnesia directory should be set to M;
- the unix DISPLAY environment variable should be set to the display of the master
  node.

The following code is executed to achieve this:

\begin{verbatim}
E = " -env DISPLAY " ++ net_adm:localhost() ++ ":0 ",
Arg = "-mnesia_dir " ++ M ++ " -pa " ++ Dir ++ E,
slave:start(H, Name, Arg).
\end{verbatim}

The start/3 call returns \{ok, Name@Host\} if successful, otherwise \{error, Reason\}. Reason can be one of:

- \texttt{timeout} The master node failed to get in contact with the slave node. This can happen
  in a number of circumstances:
  - Erlang/OTP is not installed on the remote host
  - the file system on the other host has a different structure to the the master
  - the Erlang nodes have different cookies.
- \texttt{no_rsh} There is no rsh program on the computer.
- \{already_running, Name@Host\} A node with the name Name@Host already exists.

\begin{verbatim}
start_link(Host, Name, Args)
\end{verbatim}
slave

Starts a slave node on the host Host in the same way as the start/3, except that the slave node is linked to the currently executing process. If that process terminates, the slave node also terminates.

Return value: see start/3.

stop(Node)

Stops (kills) a node.

pseudo([Master | ServerList])

Calls pseudo(Master, ServerList). If we want to start a node from the command line and set up a number of pseudo servers, an Erlang runtime system can be started as follows:

% erl -name abc -s slave pseudo klacke@super x --

pseudo(Master, ServerList)

Starts a number of pseudo servers. A pseudo server is a server with a registered name which does absolutely nothing but pass on all message to the real server which executes at a master node. A pseudo server is an intermediary which only has the same registered name as the real server.

For example, if we have started a slave node N and want to execute pxw graphics code on this node, we can start the server pxw_server as a pseudo server at the slave node. The following code illustrates:

rpc:call(N, slave, pseudo, [node(), [pxw_server]]).

relay(Pid)

Runs a pseudo server. This function never returns any value and the process which executes the function will receive messages. All messages received will simply be passed on to Pid.
The sofs module implements operations on finite sets and relations represented as sets. Intuitively, a set is a collection of elements; every element belongs to the set, and the set contains every element.

Given a set $A$ and a sentence $S(x)$, where $x$ is a free variable, a new set $B$ whose elements are exactly those elements of $A$ for which $S(x)$ holds can be formed, this is denoted $B = \{ x \in A : S(x) \}$. Sentences are expressed using the logical operators “for some” (or “there exists”), “for all”, “and”, “or”, “not”. If the existence of a set containing all the specified elements is known (as will always be the case in this module), we write $B = \{ x : S(x) \}$.

The unordered set containing the elements $a$, $b$ and $c$ is denoted $\{ a, b, c \}$. This notation is not to be confused with tuples. The ordered pair of $a$ and $b$, with first coordinate $a$ and second coordinate $b$, is denoted $(a, b)$. An ordered pair is an ordered set of two elements. In this module ordered sets can contain one, two or more elements, and parentheses are used to enclose the elements. Unordered sets and ordered sets are orthogonal, again in this module; there is no unordered set equal to any ordered set.

The set that contains no elements is called the empty set. If two sets $A$ and $B$ contain the same elements, then $A$ is equal to $B$, denoted $A = B$. Two ordered sets are equal if they contain the same number of elements and have equal elements at each coordinate. If a set $A$ contains all elements that $B$ contains, then $B$ is a subset of $A$. The union of two sets $A$ and $B$ is the smallest set that contains all elements of $A$ and all elements of $B$. The intersection of two sets $A$ and $B$ is the set that contains all elements of $A$ that belong to $B$. Two sets are disjoint if their intersection is the empty set. The difference of two sets $A$ and $B$ is the set that contains all elements of $A$ that do not belong to $B$. The symmetric difference of two sets is the set that contains those elements that belong to either of the two sets, but not both. The union of a collection of sets is the smallest set that contains all the elements that belong to at least one set of the collection. The intersection of a non-empty collection of sets is the set that contains all elements that belong to every set of the collection.

The Cartesian product of two sets $X$ and $Y$, denoted $X \times Y$, is the set $\{ a : a = (x, y) \text{ for some } x \in X \text{ and for some } y \in Y \}$. A relation is a subset of $X \times Y$. Let $R$ be a relation. The fact that $(x, y)$ belongs to $R$ is written as $x R y$. Since relations are sets, the definitions of the last paragraph (subset, union, and so on) apply to relations as well. The domain of $R$ is the set $\{ x : x R y \text{ for some } y \in Y \}$. The range of $R$ is the set $\{ y : x R y \text{ for some } x \in X \}$. The converse of $R$ is the set $\{ a : a = (y, x) \text{ for some } (x, y) \in R \}$. If $A$ is a subset of $X$, then the image of $A$ under $R$ is the set $\{ y : x R y \text{ for some } x \in A \}$, and if $B$ is a subset of $Y$, then the inverse image of $B$ is the set $\{ x : x R y \text{ for some } y \in B \}$. If $R$ is a relation from $X$ to $Y$ and $S$ is a relation from $Y$ to $Z$, then the relative product of $R$ and $S$ is the relation $T$ from $X$ to $Z$ defined so that $x T z$ if and only if there exists an element $y$ in $Y$ such that $x R y$ and $y S z$. The restriction of $R$ to $A$ is the set $S$ defined so that $x S y$ if and only if there exists an element $x$ in $A$ such that $x R y$. If $S$ is a restriction of $R$ to $A$, then $R$ is an extension of $S$ to $X$. If $X = Y$ then we call $R$ a relation.
The field of a relation \( R \) in \( X \) is the union of the domain of \( R \) and the range of \( R \). If \( R \) is a relation in \( X \), and if \( S \) is defined so that \( x \ S y \) if \( x \ R y \) and not \( x = y \), then \( S \) is the strict relation corresponding to \( R \), and vice versa, if \( S \) is a relation in \( X \), and if \( R \) is defined so that \( x \ R y \) if \( x \ S y \) or \( x = y \), then \( R \) is the weak relation corresponding to \( S \). A relation \( R \) in \( X \) is reflexive if \( x \ R x \) for every element \( x \) of \( X \); it is symmetric if \( x \ R y \) implies that \( y \ R x \); and it is transitive if \( x \ R y \) and \( y \ R z \) imply that \( x \ R z \).

A function \( F \) is a relation, a subset of \( X \times Y \), such that the domain of \( F \) is equal to \( X \) and such that for every \( x \) in \( X \) there is a unique element \( y \) in \( Y \) with \( (x, y) \) in \( F \). The latter condition can be formulated as follows: if \( x \ F y \) and \( x \ F z \) then \( y = z \). In this module, it will not be required that the domain of \( F \) be equal to \( X \) for a relation to be considered a function. Instead of writing \( (x, y) \) in \( F \) or \( x \ F y \), we write \( F(x) = y \) when \( F \) is a function, and say that \( F \) maps \( x \) onto \( y \), or that the value of \( F \) at \( x \) is \( y \). Since functions are relations, the definitions of the last paragraph (domain, range, and so on) apply to functions as well. If the converse of a function \( F \) is a function \( F' \), then \( F' \) is called the inverse of \( F \). The relative product of two functions \( F1 \) and \( F2 \) is called the composite of \( F1 \) and \( F2 \) if the range of \( F1 \) is a subset of the domain of \( F2 \).

Sometimes, when the range of a function is more important than the function itself, the function is called a family. The domain of a family is called the index set, and the range is called the indexed set. If \( x \) is a family from \( I \) to \( X \), then \( x[i] \) denotes the value of the function at index \( i \). The notation “a family in \( X \)” is used for such a family. When the indexed set is a set of subsets of a set \( X \), then we call \( x \) a family of subsets of \( X \). If \( x \) is a family of subsets of \( X \), then the union of the range of \( x \) is called the union of the family \( x \). If \( x \) is non-empty (the index set is non-empty), the intersection of the family \( x \) is the intersection of the range of \( x \). In this module, the only families that will be considered are families of subsets of some set \( X \); in the following the word “family” will be used for such families of subsets.

A partition of a set \( X \) is a collection \( S \) of non-empty subsets of \( X \) whose union is \( X \) and whose elements are pairwise disjoint. A relation in a set is an equivalence relation if it is reflexive, symmetric and transitive. If \( R \) is an equivalence relation in \( X \), and \( x \) is an element of \( X \), the equivalence class of \( x \) with respect to \( R \) is the set of all those elements \( y \) of \( X \) for which \( x \ R y \) holds. The equivalence classes constitute a partitioning of \( X \). Conversely, if \( C \) is a partition of \( X \), then the relation that holds for any two elements of \( X \) if they belong to the same equivalence class, is an equivalence relation induced by the partition \( C \). If \( R \) is an equivalence relation in \( X \), then the canonical map is the function that maps every element of \( X \) onto its equivalence class.

Relations as defined above (as sets of ordered pairs) will from now on be referred to as binary relations. We call a set of ordered sets \((x[1], \ldots, x[n])\) an \((n\text{-ary})\) relation, and say that the relation is a subset of the Cartesian product \( X[1] \times \ldots \times X[n] \) where \( x[i] \) is an element of \( X[i] \), \( 1 \leq i \leq n \). The projection of an \( n \)-ary relation \( R \) onto coordinate \( i \) is the set \( \{x[i] : (x[1], \ldots, x[i], \ldots, x[n]) \text{ in } R \text{ for some } x[j] \text{ in } X[j], \ 1 \leq j \leq n \text{ and not } i = j \} \). The projections of a binary relation \( R \) onto the first and second coordinates are the domain and the range of \( R \) respectively. The relative product of binary relations can be generalized to \( n \)-ary relations as follows. Let \( TR \) be an ordered set \((R[1], \ldots, R[n])\) of binary relations from \( X \) to \( Y[i] \) and \( S \) a binary relation from \((Y[1] \times \ldots \times Y[n])\) to \( Z \). The relative product of \( TR \) and \( S \) is the binary relation \( T \) from \( X \) to \( Z \) defined so that \( x \ T z \) if and only if there exists an element \( y[i] \) in \( Y[i] \) for each \( 1 \leq i \leq n \) such that \( x \ R[i] y[i] \) and \( (y[1], \ldots, y[n]) \text{ S z} \). Now let \( TR \) be an ordered set \((R[1], \ldots, R[n])\) of binary relations from \( X[1] \) to \( Y[1] \) and \( S \) a subset of \( X[1] \times \ldots \times X[n] \). The multiple relative product of \( TR \) and \( S \) is defined to be the set \( \{z : z = ((x[1], \ldots, x[n]), (y[1], \ldots, y[n])) \text{ for some } (x[1], \ldots, x[n]) \text{ in } S \text{ and for some } (x[i], y[i]) \text{ in } R[i], \ 1 \leq i \leq n \} \). The natural join of an \( n \)-ary relation \( R \) and an \( m \)-ary relation \( S \) on
coordinate \( i \) and \( j \) is defined to be the set \( \{ z : z = (x[1], ..., x[n], y[1], ..., y[j-1], y[j+1], ..., y[m]) \} \) for some \( (x[1], ..., x[n]) \) in \( R \) and for some \( (y[1], ..., y[m]) \) in \( S \) such that \( x[i] = y[j] \).

The sets recognized by this module will be represented by elements of the relation \( \text{Sets} \), defined as the smallest set such that:

- for every atom \( T \) except ‘\(-\)’ and for every term \( X \), \( (T, X) \) belongs to \( \text{Sets} \) (atomic sets);
- \( (\{'-\'}, []) \) belongs to \( \text{Sets} \) (the untyped empty set);
- for every tuple \( T = \{T[1], ..., T[n]\} \) and for every tuple \( X = \{X[1], ..., X[n]\} \), if \( (T[i], X[i]) \) belongs to \( \text{Sets} \) for every \( 1 \leq i \leq n \) then \( (T, X) \) belongs to \( \text{Sets} \) (ordered sets);
- for every term \( T \), if \( X \) is the empty list or a non-empty sorted list \( [X[1], ..., X[n]] \) without duplicates such that \( (T, X[i]) \) belongs to \( \text{Sets} \) for every \( 1 \leq i \leq n \), then \( ([T], X) \) belongs to \( \text{Sets} \) (typed unordered sets).

An external set is an element in the range of \( \text{Sets} \). A type is an element in the domain of \( \text{Sets} \). If \( S \) is an element \( (T, X) \) of \( \text{Sets} \), then \( T \) is a valid type of \( X \), \( T \) is the type of \( S \), and \( X \) is the external set of \( S \). from_term/2 [page 240] creates a set from a type and an Erlang term turned into an external set.

The actual sets represented by \( \text{Sets} \) are the elements of the range of the function \( \text{Set} \) from \( \text{Sets} \) to Erlang terms and sets of Erlang terms:

- \( \text{Set}(T, \text{Term}) = \text{Term} \), where \( T \) is an atom;
- \( \text{Set}(\{T[1], ..., T[n]\}, \{X[1], ..., X[n]\}) = (\text{Set}(T[1], X[1]), ..., \text{Set}(T[n], X[n])) \);
- \( \text{Set}([T], [X[1], ..., X[n]]) = (\text{Set}(T, X[1]), ..., \text{Set}(T, X[n])) \);
- \( \text{Set}([T], []) = \{\} \).

When there is no risk of confusion, elements of \( \text{Sets} \) will be identified with the sets they represent. For instance, if \( U \) is the result of calling union/2 with \( S1 \) and \( S2 \) as arguments, then \( U \) is said to be the union of \( S1 \) and \( S2 \). A more precise formulation would be that \( \text{Set}(U) \) is the union of \( \text{Set}(S1) \) and \( \text{Set}(S2) \).

The types are used to implement the various conditions that sets need to fulfill. As an example, consider the relative product of two sets \( R \) and \( S \), and recall that the relative product of \( R \) and \( S \) is defined if \( R \) is a binary relation to \( Y \) and \( S \) is a binary relation from \( Y \). The function that implements the relative product, relative_product/2 [page 247], checks that the arguments represent binary relations by matching \([A,B]\) against the type of the first argument \( \text{Arg1} \) (say), and \([C,D]\) against the type of the second argument \( \text{Arg2} \) (say). The fact that \([A,B]\) matches the type of \( \text{Arg1} \) is to be interpreted as \( \text{Arg1} \) representing a binary relation from \( X \) to \( Y \), where \( X \) is defined as all sets \( \text{Set}(x) \) for some element \( x \) in \( S \) the type of which is \( A \), and similarly for \( Y \). In the same way \( \text{Arg2} \) is interpreted as representing a binary relation from \( W \) to \( Z \). Finally it is checked that \( B \) matches \( C \), which is sufficient for ensuring that \( W \) is equal to \( Y \). The untyped empty set is handled separately: its type, ‘\(-\)’, matches the type of any unordered set.

A few functions of this module (drestriction/3, family_projection/2, partition/2, partition_family/2, projection/2, restriction/3, substitution/2) accept Erlang functions as a means to modify each element of a given unordered set. Such a function, called \( \text{SetFun} \) in the following, can be specified as a function, a tuple \( \{\text{external, Fun}\} \), or an integer. The two latter alternatives are
optimizations; instead of a set, the argument presented to the function is an external
set, which in the present implementation can be done more efficiently. This
optimization can however only be applied when the elements of the unordered set are
atomic or ordered sets. It must also be the case that the type of the elements matches
some clause of Fun (the type of the created set is the result of applying Fun to the type
of the given set), and that Fun does nothing but selecting, duplicating or rearranging
parts of the elements. Specifying a SetFun as an integer I is equivalent to specifying
\{external, fun(X) -> element(I, X)\}, but is to be preferred since it makes it
possible to handle this case even more efficiently. Examples of SetFuns:

\{sofs, union\}
fun(S) -> sofs:partition(I, S) end
\{external, fun(A) -> A end\}
\{external, fun([A, _, C]) -> [C, A] end\}
\{external, fun([_, [C]]) -> C end\}
\{external, fun([_, [_, E]=C]) -> [E, {E, C}] end\}

2

The order in which functions are applied to elements is not specified, and may change
in future versions of sofs.

The execution time of the functions of this module is dominated by the time it takes to
sort lists. When no sorting is needed, the execution time is in the worst case
proportional to the sum of the sizes of the input arguments and the returned value. A
few functions execute in constant time: from\_external, is\_empty\_set, is\_set,
is\_sofs\_set, to\_external, type.

The functions of this module exit the process with a badarg, bad\_function, or
type\_mismatch message when given badly formed arguments or sets the types of which
are not compatible.

Types

anyset() = - an unordered, ordered or atomic set -
binary\_relation() = - a binary relation -
bool() = true | false
external\_set() = - an external set -
family() = - a family (of subsets) -
function() = - a function -
ordset() = - an ordered set -
relation() = - an n-ary relation -
set() = - an unordered set -
set\_of\_sets() = - an unordered set of set() -
set\_fun() = integer() \geq 1
    | {external, fun(external\_set()) -> external\_set()}  \}
    | fun(anyset()) -> anyset()
spec\_fun() = {external, fun(external\_set()) -> bool()}
    | fun(anyset()) -> bool()
type() = - a type -

Exports

a\_function(Tuples [], Type) -> Function
Types:
• Function = function()
• Tuples = [tuple()]
• Type = type()

Creates a function [page 230]. a_function(F, T) is equivalent to from_term(F, T), if
the result is a function. If no type [page 231] is explicitly given, [{atom, atom}] is
used as type of the function.

canonical_relation(SetOfSets) -> BinRel

Types:
• BinRel = binary_relation()
• SetOfSets = set_of_sets()

Returns the binary relation containing the elements (E, Set) such that Set belongs to
SetOfSets and E belongs to Set. If SetOfSets is a partition [page 230] of a set X and R
is the equivalence relation in X induced by SetOfSets, then the returned relation is the
canonical map [page 230] from X onto the equivalence classes with respect to R.

1> Ss = sofs:from_term([[a,b],[b,c]]),
   CR = sofs:canonical_relation(Ss),
   sofs:to_external(CR).
   [{a,[a,b]},{b,[a,b]},{b,[b,c]},{c,[b,c]}]

composite(Function1, Function2) -> Function3

Types:
• Function1 = Function2 = Function3 = function()

Returns the composite [page 230] of the functions Function1 and Function2.

1> F1 = sofs:a_function([[1],[a,1],[b,2],[c,2]]),
   F2 = sofs:a_function([[1,x],[2,y],[3,z]]),
   F = sofs:composite(F1, F2),
   sofs:to_external(F).
   [{a,x},{b,y},{c,y}]

constant_function(Set, AnySet) -> Function

Types:
• AnySet = anyset()
• Function = function()
• Set = set()

Creates the function [page 230] that maps each element of the set Set onto AnySet.

1> S = sofs:set([a,b]),
   E = sofs:from_term(1),
   R = sofs:constant_function(S, E),
   sofs:to_external(R).
   [{a,1},{b,1}]

converse(BinRel1) -> BinRel2

Types:
• BinRel1 = BinRel2 = binary_relation()
Returns the converse [page 229] of the binary relation BinRel1.

1> R1 = sofs:relation([[1,a],[2,b],[3,a]]),
   R2 = sofs:converse(R1),
   sofs:to_external(R2).
   [{a,1},{a,3},{b,2}]

difference(Set1, Set2) -> Set3

Types:
- Set1 = Set2 = Set3 = set()

Returns the difference [page 229] of the sets Set1 and Set2.

digraph_to_family(Graph [, Type]) -> Family

Types:
- Graph = digraph() - see digraph(3) -
- Family = family()
- Type = type()

Creates a family [page 230] from the directed graph Graph. Each vertex a of Graph is
represented by a pair (a, [b[1], ..., b[n]]) where the b[i]'s are the out-neighbours of a.
If no type is explicitly given, [[atom, [atom]]] is used as type of the family. It is
assumed that Type is a valid type [page 231] of the external set of the family.

If G is a directed graph, it holds that the vertices and edges of G are the same as the
vertices and edges of family_to_digraph(digraph_to_family(G)).

domain(BinRel) -> Set

Types:
- BinRel = binary_relation()
- Set = set()

Returns the domain [page 229] of the binary relation BinRel.

1> R = sofs:relation([[1,a],[1,b],[2,b],[2,c]]),
   S = sofs:domain(R),
   sofs:to_external(S).
   [1,2]

drestriction(BinRel1, Set) -> BinRel2

Types:
- BinRel1 = BinRel2 = binary_relation()
- Set = set()

Returns the difference between the binary relation BinRel1 and the restriction [page
229] of BinRel1 to Set.

1> R1 = sofs:relation([[1,a],[2,b],[3,c]]),
   S = sofs:set([2,4,6]),
   R2 = sofs:drestriction(R1, S),
   sofs:to_external(R2).
   [{1,a},{3,c}]
drestriction(R, S) is equivalent to difference(R, restriction(R, S)).

drestriction(SetFun, Set1, Set2) -> Set3

Types:
- SetFun = set_fun()
- Set1 = Set2 = Set3 = set()

Returns a subset of Set1 containing those elements that do not yield an element in Set2 as the result of applying SetFun.

```declare
SetFun = {external, fun([A,B,C]) -> [B,C] end},
R1 = sofs:relation([[a,aa,1],[b,bb,2],[c,cc,3]]),
R2 = sofs:relation([[bb,2],[cc,3],[dd,4]]),
R3 = sofs:drestriction(SetFun, R1, R2),
sofs:to_external(R3).
[[a,aa,1]]
```

drestriction(F, S1, S2) is equivalent to difference(S1, restriction(F, S1, S2)).

empty_set() -> Set

Types:
- Set = set()

Returns the untyped empty set. `empty_set()` is equivalent to `from_term([], []).`

extension(BinRel1, Set, AnySet) -> BinRel2

Types:
- AnySet = anyset()
- BinRel1 = BinRel2 = binary_relation()
- Set = set()

Returns the extension of BinRel1 such that for each element E in Set that does not belong to the domain of BinRel1, BinRel2 contains the pair (E, AnySet).

```declare
S = sofs:set([b,c]),
A = sofs:empty_set(),
R = sofs:family([[a,[1,2]],[b,[3]]]),
X = sofs:extension(R, S, A),
sofs:to_external(X).
[[a,[1,2]],[b,[3]],[c,[]]]
```

family(Tuples [, Type]) -> Family

Types:
- Family = family()
- Tuples = [tuple()]
- Type = type()
family_difference(Family1, Family2) -> Family3

Types:
• Family1 = Family2 = Family3 = family()
If Family1 and Family2 are families [page 230], then Family3 the family such that the
index set is equal to the index set of Family1, and Family3[i] is the difference between
Family1[i] and Family2[i] if Family2 maps i, Family1[i] otherwise.

1> F1 = sofs:family([[a,[1,2]],[b,[3,4]]),
F2 = sofs:family([[b,[4,5]],[c,[6,7]]),
F3 = sofs:family_difference(F1, F2),
sofs:to_external(F3).

[[a,[1,2]],[b,[3]]]

family_domain(Family1) -> Family2

Types:
• Family1 = Family2 = family()
If Family1 is a family [page 230] and Family1[i] is a binary relation for every i in the
index set of Family1, then Family2 is the family with the same index set as Family1
such that Family2[i] is the domain [page 229] of Family1[i].

1> FR = sofs:from_term([[a,[[1,a],[2,b],[3,c]]],[b,[]],[c,[[4,d],[5,e]]))],
F = sofs:family_domain(FR),
sofs:to_external(F).

[[a,[1,2,3]],[b,[]],[c,[4,5]]]

family_field(Family1) -> Family2

Types:
• Family1 = Family2 = family()
If Family1 is a family [page 230] and Family1[i] is a binary relation for every i in the
index set of Family1, then Family2 is the family with the same index set as Family1
such that Family2[i] is the field [page 230] of Family1[i].

1> FR = sofs:from_term([[a,[[1,a],[2,b],[3,c]]],[b,[]],[c,[[4,d],[5,e]]))],
F = sofs:family_field(FR),
sofs:to_external(F).

[[a,[1,2,3,a,b,c]],[b,[]],[c,[4,5,d,e]]]

family_field(Family1) is equivalent to family_union(family_domain(Family1),
family_range(Family1)).

family_intersection(Family1) -> Family2

Types:
• Family1 = Family2 = family()
If Family1 is a family [page 230] and Family1[i] is a set of sets for every i in the index set of Family1, then Family2 is the family with the same index set as Family1 such that Family2[i] is the intersection [page 229] of Family1[i].

If Family1[i] is an empty set for some i, then the process exits with a \texttt{badarg} message.

1> F1 = sofs:from_term([[a,[[1,2,3],[2,3,4]]],[b,[[x,y,z],[x,y,1]]]),
   F2 = sofs:family_intersection(F1),
   sofs:to_external(F2).
   [{a,[2,3]}, {b,[x,y]}]

\textbf{family_intersection}(Family1, Family2) \to \textbf{Family3}

\textbf{Types:}
- Family1 = Family2 = Family3 = family()

If Family1 and Family2 are families [page 230], then Family3 is the family such that the index set is the intersection of Family1's and Family2's index sets, and Family3[i] is the intersection of Family1[i] and Family2[i].

1> F1 = sofs:family([[a,[[1,2]],[b,[[3,4]]],[c,[[5,6]]]]),
   F2 = sofs:family([[b,[[4,5]]],[c,[[7,8]]],[d,[[9,10]]]]),
   F3 = sofs:family_intersection(F1, F2),
   sofs:to_external(F3).
   [{b,[4]},{c,[]}]

\textbf{family_projection}(SetFun, Family1) \to \textbf{Family2}

\textbf{Types:}
- SetFun = set_fun()
- Family1 = Family2 = family()
- Set = set()

If Family1 is a family [page 230] then Family2 is the family with the same index set as Family1 such that Family2[i] is the result of calling SetFun with Family1[i] as argument.

1> F1 = sofs:from_term([[[a,[[1,2]],[2,3]],[b,[[3]]]]),
   F2 = sofs:family_projection({sofs, union}, F1),
   sofs:to_external(F2).
   [{a,[1,2,3]},{b,[1]}]

\textbf{family_range}(Family1) \to \textbf{Family2}

\textbf{Types:}
- Family1 = Family2 = family()

If Family1 is a family [page 230] and Family1[i] is a binary relation for every i in the index set of Family1, then Family2 is the family with the same index set as Family1 such that Family2[i] is the range [page 229] of Family1[i].

1> FR = sofs:from_term([[[a,[[1,a]],[2,b],[3,c]]],[b,[]],[c,[[4,d],[5,e]]]]),
   F = sofs:family_range(FR),
   sofs:to_external(F).
   [{a,[a,b,c]},{b,[]},{c,[d,e]}]

\textbf{family_specification}(Fun, Family1) \to \textbf{Family2}
Types:
- Fun = spec_fun()
- Family1 = Family2 = family()

If Family1 is a family [page 230], then Family2 is the restriction [page 229] of Family1 to those elements i of the index set for which Fun applied to Family1[i] returns true. If Fun is a tuple {external, Fun2}, Fun2 is applied to the external set [page 231] of Family1[i], otherwise Fun is applied to Family1[i].

1> F1 = sofs:family([[a,[1,2,3]], [b,[1,2]], [c,[1]]]),
SpecFun = fun(S) -> sofs:no_elements(S) == 2 end,
F2 = sofs:family_specification(SpecFun, F1),
sofs:to_external(F2).

family_to digraph(Family [, GraphType]) -> Graph

Types:
- Graph = digraph()
- Family = family()
- GraphType = - see digraph(3) -

Creates a directed graph from the family [page 230] Family. For each pair (a, [b[1], ..., b[n]]) of Family, the vertex a as well the edges (a, b[i]) for 1 <= i <= n are added to a newly created directed graph.

If no graph type is given, digraph:new/1 is used for creating the directed graph, otherwise the GraphType argument is passed on as second argument to digraph:new/2.

If F is a family, it holds that F is a subset of digraph_to_family(family_to digraph(F), type(F)). Equality holds if union_of_family(F) is a subset of domain(F).

Creating a cycle in an acyclic graph exits the process with a cyclic message.

family_to relation(Family) -> BinRel

Types:
- Family = family()
- BinRel = binary_relation()

If Family is a family [page 230], then BinRel is the binary relation containing all pairs (i, x) such that i belongs to the index set of Family and x belongs to Family[i].

1> F = sofs:family([[a[], [b]], [c, [2,3]]]),
R = sofs:family_to relation(F),
sofs:to_external(R).

family_union(Family1) -> Family2

Types:
- Family1 = Family2 = family()

If Family1 is a family [page 230] and Family1[i] is a set of sets for each i in the index set of Family1, then Family2 is the family with the same index set as Family1 such that Family2[i] is the union [page 229] of Family1[i].
family_union(Family1, Family2) -> Family3

Types:
- Family1 = Family2 = Family3 = family()

If Family1 and Family2 are families [page 230], then Family3 is the family such that the index set is the union of Family1's and Family2's index sets, and Family3[i] is the union of Family1[i] and Family2[i] if both maps i, Family1[i] or Family2[i] otherwise.

field(BinRel) -> Set

Types:
- BinRel = binary_relation()
- Set = set()

Returns the field [page 230] of the binary relation BinRel.

from_external(ExternalSet, Type) -> AnySet

Types:
- ExternalSet = external_set()
- AnySet = anyset()
- Type = type()

Creates a set from the external set [page 231] ExternalSet and the type [page 231] Type. It is assumed that Type is a valid type [page 231] of ExternalSet.

from_sets(ListOfSets) -> Set

Types:
- Set = set()
- ListOfSets = [anyset()]

Returns the unordered set [page 231] containing the sets of the list ListOfSets.
\[ S1 = \text{sofs:relation}([\{a,1\},\{b,2\}]), \]
\[ S2 = \text{sofs:relation}([\{x,3\},\{y,4\}]), \]
\[ S = \text{sofs:from_sets}(\{S1, S2\}), \]
\[ \text{sofs:to_external}(S). \]

\[
[[\{a,1\},\{b,2\}],[\{x,3\},\{y,4\}]]
\]

\[
\text{from_sets}((\text{TupleOfSets}) \to \text{Ordset})
\]

**Types:**
- Ordset = \text{ordset()}
- TupleOfSets = tuple-of(\text{anyset()})

Returns the ordered set [page 231] containing the sets of the non-empty tuple TupleOfSets.

\[
\text{from_term}(\text{Term} [, \text{Type}]) \to \text{AnySet}
\]

**Types:**
- AnySet = \text{anyset()}
- Term = \text{term()}
- Type = \text{type()}

Creates an element of \text{Sets} [page 231] by traversing the term Term, sorting lists, removing duplicates and deriving or verifying a valid type [page 231] for the so obtained external set. An explicitly given type [page 231] Type can be used to limit the depth of the traversal; an atomic type stops the traversal, as demonstrated by this example where "foo" and "foo" are left unmodified:

\[
S = \text{sofs:from_term}([[\text{"foo"}],[1,1]],[\text{"foo"},{2,2}]), \text{sofs:to_external}(S).
[[\text{"foo"}],[1],[\text{"foo"},{2}]]
\]

\text{from_term} can be used for creating atomic or ordered sets. The only purpose of such a set is that of later building unordered sets since all functions in this module that do anything operate on unordered sets. Creating unordered sets from a collection of ordered sets may be the way to go if the ordered sets are big and one does not want to waste heap by rebuilding the elements of the unordered set. An example showing that a set can be built "layer by layer":

\[
A = \text{sofs:from_term}(a), \]
\[ S = \text{sofs:set}([1,2,3]), \]
\[ P1 = \text{sofs:from_sets}([A,S]), \]
\[ P2 = \text{sofs:from_term}([b,[6,5,4]]), \]
\[ Ss = \text{sofs:from_sets}([P1,P2]), \]
\[ \text{sofs:to_external}(Ss). \]
\[ [{\{a,[1,2,3]\}},{\{b,[4,5,6]\}]} \]

Other functions that create sets are \text{from_external}/2 and \text{from_sets}/1. Special cases of \text{from_term}/2 are \text{a_function}/1,2, \text{empty_set}/0, \text{family}/1,2, \text{relation}/1,2, and \text{set}/1,2.

\[
\text{image}((\text{BinRel}, \text{Set}1) \to \text{Set}2)
\]

**Types:**
- BinRel = \text{binary_relation()}

\[ \]
- Set1 = Set2 = set()

Returns the image [page 229] of the set Set1 under the binary relation BinRel.

```prolog
1> R = sofs:relation([[1,a],[2,b],[2,c],[3,d]]),
   S1 = sofs:set([1,2]),
   S2 = sofs:image(R, S1),
   sofs:to_external(S2).
[a,b,c]
```

**intersection(SetOfSets) -> Set**

Types:
- Set = set()
- SetOfSets = set() of sets()

Returns the intersection [page 229] of the set of sets SetOfSets.
Intersecting an empty set of sets exits the process with a badarg message.

```prolog
intersection(Set1, Set2) -> Set3

Types:
- Set1 = Set2 = Set3 = set()

Returns the intersection [page 229] of Set1 and Set2.
```

**intersection_of_family(Family) -> Set**

Types:
- Family = family()
- Set = set()

Returns the intersection of the family [page 230] Family.
Intersecting an empty family exits the process with a badarg message.

```prolog
1> F = sofs:family([a,[0,2,4]],[b,[0,1,2]],[c,[2,3]]),
   S = sofs:intersection_of_family(F),
   sofs:to_external(S).
[2]
```

**inverse(Function1) -> Function2**

Types:
- Function1 = Function2 = function()

Returns the inverse [page 230] of the function Function1.

```prolog
1> R1 = sofs:relation([[1,a],[2,b],[3,c]]),
   R2 = sofs:inverse(R1),
   sofs:to_external(R2).
[[a,1],[b,2],[c,3]]
```

**inverse_image(BinRel, Set1) -> Set2**

Types:
- BinRel = binary_relation()
• Set1 = Set2 = set()

Returns the inverse image [page 229] of Set1 under the binary relation BinRel.

1> R = sofs:relation([[1,a],[2,b],[2,c],[3,d]]),
   S1 = sofs:set([c,d,e]),
   S2 = sofs:inverse_image(R, S1),
   sofs:to_external(S2).
[2,3]

is_a_function(BinRel) -> Bool
Types:
• BinRel = binary_relation()

Returns true if the binary relation BinRel is a function [page 230] or the untyped empty set, false otherwise.

is_disjoint(Set1, Set2) -> Bool
Types:
• Set1 = Set2 = set()

Returns true if Set1 and Set2 are disjoint [page 229], false otherwise.

is_empty_set(AnySet) -> Bool
Types:
• AnySet = anyset()

Returns true if Set is an empty unordered set, false otherwise.

is_equal(AnySet1, AnySet2) -> Bool
Types:
• AnySet1 = AnySet2 = anyset()

Returns true if the AnySet1 and AnySet2 are equal [page 229], false otherwise.

is_set(AnySet) -> Bool
Types:
• AnySet = anyset()

Returns true if AnySet is an unordered set [page 231], and false if AnySet is an ordered set or an atomic set.

is_sofs_set(Term) -> Bool
Types:
• Bool = bool()
is_subset(Set1, Set2) -> Bool
Types:
- Bool = bool()
- Set1 = Set2 = set()

Returns true if Set1 is a subset [page 229] of Set2, false otherwise.

is_type(Term) -> Bool
Types:
- Bool = bool()
- Term = term()

Returns true if the term Term is a type [page 231].

join(Relation1, I, Relation2, J) -> Relation3
Types:
- Relation1 = Relation2 = Relation3 = relation()
- I = J = integer() > 0

Returns the natural join [page 230] of the relations Relation1 and Relation2 on coordinates I and J.

\[
R_1 = \text{sofs:relation}([[a,x,1],[b,y,2]]),
R_2 = \text{sofs:relation}([[1,f,g],[1,h,1],[2,3,4]]),
J = \text{sofs:join}(R_1, 3, R_2, 1),
\text{sofs:to external}(J).
\]

multiple_relative_product(TupleOfBinRels, BinRel1) -> BinRel2
Types:
- TupleOfBinRels = tuple-of(BinRel)
- BinRel = BinRel1 = BinRel2 = binary relation()

If TupleOfBinRels is a non-empty tuple \(\{R_1, ..., R[n]\}\) of binary relations and BinRel1 is a binary relation, then BinRel2 is the multiple relative product [page 230] of the ordered set \(\{R[i], ..., R[n]\}\) and BinRel1.

\[
R_1 = \text{sofs:relation}([[a,1],[b,2],[c,3]]),
R = \text{sofs:relation}([[a,b],[b,c],[c,a]]),
MP = \text{sofs:multiple_relative_product}(R_1, R),
\text{sofs:to external}(\text{sofs:range}(MP)).
\]

no_elements(ASET) -> NoElements
Types:
- ASet = set() | ordset()
NoElements = integer() >= 0
Returns the number of elements of the ordered or unordered set ASet.

partition(SetOfSets) -> Partition
Types:
- SetOfSets = set_of_sets()
- Partition = set()
Returns the partition [page 230] of the union of the set of sets SetOfSets such that two elements are considered equal if they belong to the same elements of SetOfSets.

```prolog
1> Sets1 = sofs:from_term([[a,b,c],[d,e,f],[g,h,i]]),
    Sets2 = sofs:from_term([[b,c,d],[e,f,g],[h,i,j]]),
    P = sofs:partition(sofs:union(Sets1, Sets2),
                        sofs:to_external(P).
[[[a],[b,c],[d],[e,f],[g],[h,i],[j]]]
```

partition(SetFun, Set) -> Partition
Types:
- SetFun = set_fun()
- Partition = set()
- Set = set()
Returns the partition [page 230] of Set such that two elements are considered equal if the results of applying SetFun are equal.

```prolog
1> Ss = sofs:from_term([[a],[b],[c,d],[e,f]]),
    SetFun = fun(S) -> sofs:from_term(sofs:no_elements(S)) end,
    P = sofs:partition(SetFun, Ss),
    sofs:to_external(P).
[[[a],[b]],[[c,d],[e,f]]]
```

partition(SetFun, Set1, Set2) -> {Set3, Set4}
Types:
- SetFun = set_fun()
- Set1 = Set2 = Set3 = Set4 = set()
Returns a pair of sets that, regarded as constituting a set, forms a partition [page 230] of Set1. If the result of applying SetFun to an element of Set1 yields an element in Set2, the element belongs to Set3, otherwise the element belongs to Set4.

```prolog
1> R1 = sofs:relation([[1,a],[2,b],[3,c]]),
    S = sofs:set([2,4,6]),
    [R2,R3] = sofs:partition(1, R1, S),
    [sofs:to_external(R2),sofs:to_external(R3)].
    [[{2,4}],[[1,a],[3,c]]]
partition(F, S1, S2) is equivalent to {restriction(F, S1, S2),
                                        drestriction(F, S1, S2)}.
```

partition_family(SetFun, Set) -> Family
Types:
- Family = family()
- SetFun = set_fun()
- Set = set()

Returns the family [page 230] Family where the indexed set is a partition [page 230] of Set such that two elements are considered equal if the results of applying SetFun are the same value i. This i is the index that Family maps onto the equivalence class [page 230].

```erlang
i> S = sofs:relation([[a,a,a,a],[a,a,b,b],[a,b,b,b]]),
   SetFun = {external, fun({A,C} -> {A,C} end),
   F = sofs:partition_family(SetFun, S),
   sofs:to_external(F).
[[[a,a],[[a,a,a,a]],[[a,b],[[a,a,b,b],[a,b,b,b]]]]
```

product(TupleOfSets) -> Relation

Types:
- Relation = relation()
- TupleOfSets = tuple-of(set())

Returns the Cartesian product [page 230] of the non-empty tuple of sets TupleOfSets. If (x[1], ..., x[n]) is an element of the n-ary relation Relation, then x[i] is drawn from element i of TupleOfSets.

```erlang
i> S1 = sofs:set([a,b]),
   S2 = sofs:set([1,2]),
   S3 = sofs:set([x,y]),
   P3 = sofs:product([S1,S2,S3]),
   sofs:to_external(P3).
[[[a,1],[a,1,y],[a,2,x],[a,2,y],[b,1,x],[b,1,y],[b,2,x],[b,2,y]]
```

product(Set1, Set2) -> BinRel

Types:
- BinRel = binary_relation()
- Set1 = Set2 = set()

Returns the Cartesian product [page 229] of Set1 and Set2.

```erlang
i> S1 = sofs:set([1,2]),
   S2 = sofs:set([a,b]),
   R = sofs:product(S1, S2),
   sofs:to_external(R).
[[1,a],[1,b],[2,a],[2,b]]
```

product(S1, S2) is equivalent to product([S1, S2]).

projection(SetFun, Set1) -> Set2

Types:
- SetFun = set_fun()
- Set1 = Set2 = set()
Returns the set created by substituting each element of Set1 by the result of applying SetFun to the element.

If SetFun is a number \( i \geq 1 \) and Set1 is a relation, then the returned set is the projection [page 230] of Set1 onto coordinate \( i \).

\[
S1 = \text{sofs:from_term}([[1,a],[2,b],[3,a]]), \\
S2 = \text{sofs:projection}(2, S1), \\
\text{sofs:to_external}(S2).
\]

```
[a,b]
```

range(BinRel) -> Set

Types:
- BinRel = binary_relation()
- Set = set()

Returns the range [page 229] of the binary relation BinRel.

\[
R = \text{sofs:relation}([[1,a],[1,b],[2,b],[2,c]]), \\
S = \text{sofs:range}(R), \\
\text{sofs:to_external}(S).
\]

```
[a,b,c]
```

relation(Tuples [, Type]) -> Relation

Types:
- \( N \) = integer()
- Type = \( N \ | \text{type}() \)
- Relation = relation()
- Tuples = [tuple()]

Creates a relation [page 229]. \( \text{relation}(R, T) \) is equivalent to \( \text{from_term}(R, T) \), if \( T \) is a type [page 231] and the result is a relation. If Type is an integer \( N \), then \( \{\text{atom, ..., atom}\} \), where the size of the tuple is \( N \), is used as type of the relation.

If no type is explicitly given, the size of the first tuple of Tuples is used if there is such a tuple. \( \text{relation}([]) \) is equivalent to \( \text{relation}([], 2) \).

```
relation_to_family(BinRel) -> Family
```

Types:
- Family = family()
- BinRel = binary_relation()

Returns the family [page 230] Family such that the index set is equal to the domain [page 229] of the binary relation BinRel, and Family[i] is the image [page 229] of the set of i under BinRel.

\[
R = \text{sofs:relation}([[b,1],[c,2],[c,3]]), \\
F = \text{sofs:relation_to_family}(R), \\
\text{sofs:to_external}(F).
\]

```
[b,[1]],[c,[2,3]]
```

relative_product(TupleOfBinRels [, BinRel1]) -> BinRel2

Types:
• TupleOfBinRels = tuple-of(BinRel)
• BinRel = BinRel1 = BinRel2 = binary_relation()

If TupleOfBinRels is a non-empty tuple \( \{R_1, ..., R_n\} \) of binary relations and BinRel1 is a binary relation, then BinRel2 is the relative product [page 230] of the ordered set \( (R[i], ..., R[n]) \) and BinRel1.

If BinRel1 is omitted, the relation of equality between the elements of the Cartesian product [page 230] of the ranges of \( R[i] \), range \( R[1] \times ... \times range R[n] \), is used instead (intuitively, nothing is "lost").

```prolog
1> TR = sofs:relation([[1,a],[1,aa],[2,b]]),
   R1 = sofs:relation([[1,u],[2,v],[3,c]]),
   R2 = sofs:relative_product([TR, R1]),
   sofs:to_external(R2).
   [{1,[a,u]},{1,[aa,u]},{2,[b,v]}]
```

Note that `relative_product([R1], R2)` is different from `relative_product(R1, R2)`; the tuple of one element is not identified with the element itself.

\textbf{relative_product}(BinRel1, BinRel2) -> BinRel3

Types:
• BinRel1 = BinRel2 = BinRel3 = binary_relation()

Returns the relative product [page 229] of the binary relations BinRel1 and BinRel2.

\textbf{relative_product1}(BinRel1, BinRel2) -> BinRel3

Types:
• BinRel1 = BinRel2 = BinRel3 = binary_relation()

Returns the relative product [page 229] of the converse [page 229] of the binary relation BinRel1 and the binary relation BinRel2.

```prolog
1> R1 = sofs:relation([[1,a],[1,aa],[2,b]]),
   R2 = sofs:relation([[1,u],[2,v],[3,c]]),
   R3 = sofs:relative_product1(R1, R2),
   sofs:to_external(R3).
   [{a,u},{aa,u},{b,v}]
```

\textbf{relative_product1}(R1, R2) is equivalent to `relative_product(converse(R1), R2)`.

\textbf{restriction}(BinRel1, Set) -> BinRel2

Types:
• BinRel1 = BinRel2 = binary_relation()
• Set = set()

Returns the restriction [page 229] of the binary relation BinRel1 to Set.

```prolog
1> R1 = sofs:relation([[1,a],[2,b],[3,c]]),
   S = sofs:set([1,2,3]),
   R2 = sofs:restriction(R1, S),
   sofs:to_external(R2).
   [{1,a},{2,b}]```
restriction(SetFun, Set1, Set2) -> Set3
Types:
- SetFun = set_fun()
- Set1 = Set2 = Set3 = set()
Returns a subset of Set1 containing those elements that yield an element in Set2 as the result of applying SetFun.

```erlang
1> S1 = sofs:relation([[1,a],[2,b],[3,c]]),
   S2 = sofs:set([b,c,d]),
   S3 = sofs:restriction(2, S1, S2),
   sofs:to_external(S3).
[[2,b],[3,c]]
```

set(Terms [, Type]) -> Set
Types:
- Set = set()
- Terms = [term()]
- Type = type()
Creates an unordered set [page 231]. set(L, T) is equivalent to from_term(L, T), if the result is an unordered set. If no type [page 231] is explicitly given, [atom] is used as type of the set.

specification(Fun, Set1) -> Set2
Types:
- Fun = spec_fun()
- Set1 = Set2 = set()
Returns the set containing every element of Set1 for which Fun returns true. If Fun is a tuple {external, Fun2}, Fun2 is applied to the external set [page 231] of each element, otherwise Fun is applied to each element.

```erlang
1> R1 = sofs:relation([[a,1],[b,2]]),
   R2 = sofs:relation([[x,1],[x,2],[y,3]]),
   S1 = sofs:from_sets([R1,R2]),
   S2 = sofs:specification([{sofs,is_a_function}, S1],
                           sofs:to_external(S2).
[[[a,1],[b,2]]]
```

strict_relation(BinRel1) -> BinRel2
Types:
- BinRel1 = BinRel2 = binary_relation()
Returns the strict relation [page 230] corresponding to the binary relation BinRel1.

```erlang
1> R1 = sofs:relation([[1,1],[1,2],[2,1],[2,2]]),
   R2 = sofs:strict_relation(R1),
   sofs:to_external(R2).
[[1,2],[2,1]]
```

substitution(SetFun, Set1) -> Set2
Types:

- SetFun = setfun()
- Set1 = Set2 = set()

Returns a function, the domain of which is Set1. The value of an element of the domain is the result of applying SetFun to the element.

1> L = [[a,1],[b,2]].
   [[a,1],[b,2]]
2> sofs:to_external(sofs:projection(1,sofs:relation(L))).
   [a,b]
3> sofs:to_external(sofs:substitution(1,sofs:relation(L))).
   [[{a,1},a],[{b,2},b]]
4> SetFun = [external, fun(A) - E) -> [E,A] end],
   sofs:to_external(sofs:projection(SetFun,sofs:relation(L))).
   [[{a,1},a],[{b,2},b]]

The relation of equality between the elements of \{a,b,c\}:

1> I = sofs:substitution(fun(A) - A end, sofs:set([a,b,c]))],
   sofs:to_external(I).
   [[a,a],[b,b],[c,c]]

Let SetOfSets be a set of sets and BinRel a binary relation. The function that maps each element Set of SetOfSets onto the image of Set under BinRel is returned by this function:

images(SetOfSets, BinRel) -
   Fun = fun(Set) -> sofs:image(BinRel, Set) end,
   sofs:substitution(Fun, SetOfSets).

Here might be the place to reveal something that was more or less stated before, namely that external unordered sets are represented as sorted lists. As a consequence, creating the image of a set under a relation R may traverse all elements of R (to that comes the sorting of results, the image). In images/2, BinRel will be traversed once for each element of SetOfSets, which may take too long. The following efficient function could be used instead under the assumption that the image of each element of SetOfSets under BinRel is non-empty:

images2(SetOfSets, BinRel) -
   CR = sofs:canonical_relation(SetOfSets),
   R = sofs:relative_product1(CR, BinRel),
   sofs:relation_to_family(R).

**symdiff(Set1, Set2) -** Set3

Types:

- Set1 = Set2 = Set3 = set()

Returns the symmetric difference (or the Boolean sum) of Set1 and Set2.

1> S1 = sofs:set([1,2,3]),
   S2 = sofs:set([2,3,4]),
   P = sofs:symdiff(S1, S2),
   sofs:to_external(P).
   [1,4]
symmetric_partition(Set1, Set2) -> {Set3, Set4, Set5}

Types:
- Set1 = Set2 = Set3 = Set4 = Set5 = set()

Returns a triple of sets: Set3 contains the elements of Set1 that do not belong to Set2; Set4 contains the elements of Set1 that belong to Set2; Set5 contains the elements of Set2 that do not belong to Set1.

to_external(AnySet) -> ExternalSet

Types:
- ExternalSet = external_set()
- AnySet = anyset()

Returns the external set [page 231] of an atomic, ordered or unordered set.

to_sets(ASet) -> Sets

Types:
- ASet = set() | ordset()
- Sets = tuple_of(AnySet) | [AnySet]

Returns the elements of the ordered set ASet as a tuple of sets, and the elements of the unordered set ASet as a sorted list of sets without duplicates.

type(AnySet) -> Type

Types:
- AnySet = anyset()
- Type = type()

Returns the type [page 231] of an atomic, ordered or unordered set.

union(SetOfSets) -> Set

Types:
- Set = set()
- SetOfSets = set_of_sets()

Returns the union [page 229] of the set of sets SetOfSets.

union(Set1, Set2) -> Set3

Types:
- Set1 = Set2 = Set3 = set()

Returns the union [page 229] of Set1 and Set2.

union_of_family(Family) -> Set

Types:
- Family = family()
- Set = set()

Returns the union of the family [page 230] Family.
weak_relation(BinRel1) -> BinRel2

Types:

- BinRel1 = BinRel2 = binary_relation()

Returns a subset $S$ of the weak relation [page 230] $W$ corresponding to the binary relation $\text{BinRel1}$. Let $F$ be the field [page 230] of $\text{BinRel1}$. The subset $S$ is defined so that $x S y$ if $x W y$ for some $x$ in $F$ and for some $y$ in $F$.

\[
\begin{align*}
1 & > \text{R1} = \text{sofs:relation}([[1,1],[1,2],[3,1]]), \\
R2 & = \text{sofs:weak_relation}(\text{R1}), \\
\text{sofs:to_external}(\text{R2}).
\end{align*}
\]

\[
[1,1],[1,2],[2,2],[3,1],[3,3]
\]

This module contains functions for string processing.

Exports

len(String) -> Length
Types:
  - String = string()
  - Length = integer()
Returns the number of characters in the string.

equal(String1, String2) -> bool()
Types:
  - String1 = String2 = string()
Tests whether two strings are equal. Returns true if they are, otherwise false.

concat(String1, String2) -> String3
Types:
  - String1 = String2 = String3 = string()
Concatenates two strings to form a new string. Returns the new string.

chr(String, Character) -> Index
rchr(String, Character) -> Index
Types:
  - String = string()
  - Character = char()
  - Index = integer()
Returns the index of the first/last occurrence of Character in String. 0 is returned if Character does not occur.

str(String, SubString) -> Index
rstr(String, SubString) -> Index
Types:
  - String = SubString = string()
- Index = integer()

  Returns the position where the first/last occurrence of SubString begins in String. 0 is returned if SubString does not exist in String. For example:

  > string: Index(" Hello Hello World World ", "Hello World").
  8

span(String, Chars) -> Length
cspan(String, Chars) -> Length

  Types:
  - String = Chars = string()
  - Length = integer()

  Returns the length of the maximum initial segment of String, which consists entirely of characters from (not from) Chars.

  For example:
  > string:span("\t abcdef", "\t").
  5
  > string:cspan("\t abcdef", "\t").
  0

substr(String, Start) -> SubString
substr(String, Start, Length) -> Substring

  Types:
  - String = SubString = string()
  - Start = Length = integer()

  Returns a substring of String, starting at the position Start, and ending at the end of the string or at length Length.

  For example:
  > substr("Hello World", 4, 5).
  "lo Wo"

tokens(String, SeparatorList) -> Tokens

  Types:
  - String = SeparatorList = string()
  - Tokens = [string()]

  Returns a list of tokens in String, separated by the characters in SeparatorList.

  For example:
  > tokens("abc defxghix jkl", "x ").
  ["abc", "def", "ghi", "jkl"]

tokens(String, SeparatorList) -> Tokens

chars(Character, Number) -> String
chars(Character, Number, Tail) -> String

  Types:
  - Character = char()
- Number = integer()
- String = string()

Returns a string consisting of Number of characters Character. Optionally, the string can end with the string Tail.

copies(String, Number) -> Copies

Types:
- String = Copies = string()
- Number = integer()

Returns a string containing String repeated Number times.

words(String) -> Count
words(String, Character) -> Count

Types:
- String = string()
- Character = char()
- Count = integer()

Returns the number of words in String, separated by blanks or Character.

For example:
> words(" Hello old boy!", $o).
   4

sub_word(String, Number) -> Word
sub_word(String, Number, Character) -> Word

Types:
- String = Word = string()
- Character = char()
- Number = integer()

Returns the word in position Number of String. Words are separated by blanks or Characters.

For example:
> string:sub_word(" Hello old boy!",3,$o).
   "ld b"

strip(String) -> Stripped
strip(String, Direction) -> Stripped
strip(String, Direction, Character) -> Stripped

Types:
- String = Stripped = string()
- Direction = left | right | both
- Character = char()
Returns a string, where leading and/or trailing blanks or a number of \texttt{Character} have been removed. Direction can be \texttt{left}, \texttt{right}, or \texttt{both} and indicates from which direction blanks are to be removed. The function \texttt{strip/1} is equivalent to \texttt{strip(String, both)}.

For example:

\begin{verbatim}
> string:strip("...Hello.....", both, $).
"Hello"
\end{verbatim}

\texttt{left(String, Number)} \rightarrow \texttt{Left}
\texttt{left(String, Number, Character)} \rightarrow \texttt{Left}

Types:
\begin{itemize}
\item String = \texttt{Left} = \texttt{string()}
\item Character = \texttt{char}
\item Number = \texttt{integer()}
\end{itemize}

Returns the \texttt{String} with the length adjusted in accordance with \texttt{Number}. The left margin is fixed. If the length(\texttt{String}) < \texttt{Number}, String is padded with blanks or \texttt{Character}s.

For example:

\begin{verbatim}
> string:left("Hello",10,$).
"Hello....."
\end{verbatim}

\texttt{right(String, Number)} \rightarrow \texttt{Right}
\texttt{right(String, Number, Character)} \rightarrow \texttt{Right}

Types:
\begin{itemize}
\item String = \texttt{Right} = \texttt{string()}
\item Character = \texttt{char}
\item Number = \texttt{integer()}
\end{itemize}

Returns the \texttt{String} with the length adjusted in accordance with \texttt{Number}. The right margin is fixed. If the length(\texttt{String}) < \texttt{Number}, String is padded with blanks or \texttt{Character}s.

For example:

\begin{verbatim}
> string:right("Hello",10,$).
".....Hello"
\end{verbatim}

\texttt{centre(String, Number)} \rightarrow \texttt{Centered}
\texttt{centre(String, Number, Character)} \rightarrow \texttt{Centered}

Types:
\begin{itemize}
\item String = \texttt{Centered} = \texttt{string()}
\item Character = \texttt{char}
\item Number = \texttt{integer()}
\end{itemize}

Returns a string, where \texttt{String} is centred in the string and surrounded by blanks or characters. The resulting string will have the length \texttt{Number}.

\texttt{sub_string(String, Start)} \rightarrow \texttt{SubString}
sub_string(String, Start, Stop) -> SubString

Types:
- String = SubString = string()
- Start = Stop = integer()

Returns a substring of String, starting at the position Start to the end of the string, or to and including the Stop position.

For example:

sub_string("Hello World", 4, 8).
"lo Wo"

Notes

Some of the general string functions may seem to overlap each other. The reason for this is that this string package is the combination of two earlier packages and all the functions of both packages have been retained.

The regular expression functions have been moved to their own module regexp (see regexp [page 210]). The old entry points still exist for backwards compatibility, but will be removed in a future release so that users are encouraged to use the module regexp.

Note:
Any undocumented functions in string should not be used.
supervisor

Erlang Module

A behaviour module for implementing a supervisor, a process which supervises other processes called child processes. A child process can either be another supervisor or a worker process. Worker processes are normally implemented using one of the gen_event, gen_fsm, or gen_server behaviours. A supervisor implemented using this module will have a standard set of interface functions and include functionality for tracing and error reporting. Supervisors are used to build an hierarchical process structure called a supervision tree, a nice way to structure a fault tolerant application. Refer to OTP Design Principles for more information.

A supervisor assumes the definition of which child processes to supervise to be located in a callback module exporting a pre-defined set of functions.

Unless otherwise stated, all functions in this module will fail if the specified supervisor does not exist or if bad arguments are given.

Supervision Principles

The supervisor is responsible for starting, stopping and monitoring its child processes. The basic idea of a supervisor is that it should keep its child processes alive by restarting them when necessary.

The children of a supervisor is defined as a list of child specifications. When the supervisor is started, the child processes are started in order from left to right according to this list. When the supervisor terminates, it first terminates its child processes in reversed start order, from right to left.

A supervisor can have one of the following restart strategies:

- **one_for_one** - if one child process terminates and should be restarted, only that child process is affected.
- **one_for_all** - if one child process terminates and should be restarted, all other child processes are terminated and then all child processes are restarted.
- **rest_for_one** - if one child process terminates and should be restarted, the ‘rest’ of the child processes - i.e. the child processes after the terminated child process in the start order - are terminated. Then the terminated child process and all child processes after it are restarted.
- **simple_one_for_one** - a simplified one_for_one supervisor, where all child processes are dynamically added instances of the same process type, i.e. running the same code.

The functions `terminate_child/2`, `delete_child/2` and `restart_child/2` are invalid for `simple_one_for_one` supervisors and will return `{error, simple_one_for_one}` if the specified supervisor uses this restart strategy.
To prevent a supervisor from getting into an infinite loop of child process terminations and restarts, a maximum restart frequency is defined using two integer values \( \text{MaxR} \) and \( \text{MaxT} \). If more than \( \text{MaxR} \) restarts occur within \( \text{MaxT} \) seconds, the supervisor terminates all child processes and then itself.

This is the type definition of a child specification:

```plaintext
child_spec() = {Id,StartFunc,Restart,Shutdown,Type,Modules}
  Id = term()
  StartFunc = {M,F,A}
    M = F = atom()
    A = [term()]
  Restart = permanent | transient | temporary
  Shutdown = brutal.kill | int()>=0 | infinity
  Type = worker | supervisor
  Modules = [Module] | dynamic
    Module = atom()
```

- \( \text{Id} \) is a name that is used to identify the child specification internally by the supervisor.
- \( \text{StartFunc} \) defines the function call used to start the child process. It should be a module-function-arguments tuple \( \{M,F,A\} \) used as \( \text{apply}(M,F,A) \).

The start function must create and link to the child process, and should return \{ok,Child\} or \{ok,Child,Info\} where Child is the pid of the child process and Info an arbitrary term which is ignored by the supervisor.

The start function can also return \ignore\ if the child process for some reason cannot be started, in which case the child specification will be kept by the supervisor but the non-existing child process will be ignored.

If something goes wrong, the function may also return an error tuple \{error,Error\}.

Note that the start_link functions of the different behaviour modules fulfill the above requirements.

- \( \text{Restart} \) defines when a terminated child process should be restarted. A permanent child process should always be restarted, a temporary child process should never be restarted and a transient child process should be restarted only if it terminates abnormally, i.e. with another exit reason than normal.
- \( \text{Shutdown} \) defines how a child process should be terminated. \text{brutal.kill} means the child process will be unconditionally terminated using \( \text{exit}(\text{Child},\text{kill}) \). An integer timeout value means that the supervisor will tell the child process to terminate by calling \( \text{exit}(\text{Child},\text{shutdown}) \) and then wait for an exit signal from the child process. If no exit signal is received within the specified time, the child process is unconditionally terminated using \( \text{exit}(\text{Child},\text{kill}) \).
  If the child process is another supervisor, \( \text{Shutdown} \) should be set to \text{infinity} to give the subtree ample time to shutdown.
- \( \text{Type} \) specifies if the child process is a supervisor or a worker.
• Modules is used by the release handler during code replacement to determine which processes are using a certain module. As a rule of thumb Modules should be a list with one element [Module], where Module is the name of the callback module, if the child process is a supervisor, gen_server or gen_fsm. If the child process is an event manager (gen_event) with a dynamic set of callback modules, Modules should be dynamic. See SASL User’s Guide for more information.

• Internally, the supervisor also keeps track of the pid Child of the child process, or undefined if no pid exists.

Exports

\[\text{start_link(Module, Args)} \rightarrow \text{Result} \]
\[\text{start_link(SupName, Module, Args)} \rightarrow \text{Result} \]

Types:
• SupName = \{local,Name\} | {global,Name}
• Name = atom()
• Module = atom()
• Args = term()
• Result = \{ok,Pid\} | ignore | \{error,Error\}
• Pid = pid()
• Error = \{already_started,Pid\} | shutdown | term()

Creates a supervisor process, linked to the calling process, which calls Module:init/1 to find out about restart strategy, maximum restart frequency and child processes. To ensure a synchronized start-up procedure, this function does not return until Module:init/1 has returned and all child processes have been started.

If SupName=\{local,Name\} the supervisor is registered locally as Name using register/2. If SupName=\{global,Name\} the supervisor is registered globally as Name using global:register_name/2. If no name is provided, the supervisor is not registered. If there already exists a process with the specified SupName the function returns \{error,\{already_started,Pid\}\}, where Pid is the pid of that process.

Module is the name of the callback module.

Args is an arbitrary term which is passed as the argument to Module:init/1.

If the supervisor and its child processes are successfully created (i.e. if all child process start functions return \{ok,Child\}, \{ok,Child,Info\}, or ignore) the function returns \{ok,Pid\}, where Pid is the pid of the supervisor.

If Module:init/1 returns ignore, this function returns ignore as well and the supervisor terminates with reason normal. If Module:init/1 fails or returns an incorrect value, this function returns \{error,Term\} where Term is a term with information about the error, and the supervisor terminates with reason Term.

If any child process start function fails or returns an error tuple or an erroneous value, the function returns \{error,shutdown\} and the supervisor terminates all started child processes and then itself with reason shutdown.

\[\text{start_child(SupRef, ChildSpec)} \rightarrow \text{Result} \]

Types:
Dynamically adds a child specification to the supervisor `SupRef` which starts the corresponding child process.

`SupRef` can be:

- the pid,
- `Name`, if the supervisor is locally registered,
- `{Name,Node}`, if the supervisor is locally registered at another node, or
- `{global,Name}`, if the supervisor is globally registered.

`ChildSpec` should be a valid child specification (unless the supervisor is a `simple_one_for_one` supervisor, see below). The child process will be started by using the start function as defined in the child specification.

If the case of a `simple_one_for_one` supervisor, the child specification defined in `Module:init/1` will be used and `ChildSpec` should instead be an arbitrary list of terms `List`. The child process will then be started by appending `List` to the existing start function arguments, i.e. by calling `apply(M, F, A++List)` where `{M,F,A}` is the start function defined in the child specification.

If there already exists a child specification with the specified `Id`, `ChildSpec` is discarded and the function returns `{error,already_present}` or `{error,already_started,Child}`, depending on if the corresponding child process is running or not.

If the child process start function returns `{ok,Child}` or `{ok,Child,Info}`, the child specification and pid is added to the supervisor and the function returns the same value.

If the child process start function returns `ignore`, the child specification is added to the supervisor, the pid is set to `undefined` and the function returns `{ok,undefined}`.

If the child process start function returns an error tuple or an erroneous value, or if it fails, the child specification is discarded and the function returns `error/Error` where `Error` is a term containing information about the error and child specification.

```prolog
terminate_child(SupRef, Id) -> Result
```

Types:

- `SupRef = Name | {Name,Node} | {global,Name} | pid()`
- `Name = Node = atom()`
- `Id = term()`
- `Result = ok | {error,Error}`
- `Error = not_found | simple_one_for_one`
Tells the supervisor SupRef to terminate the child process corresponding to the child specification identified by Id. The process, if there is one, is terminated but the child specification is kept by the supervisor. This means that the child process may be later be restarted by the supervisor. The child process can also be restarted explicitly by calling restart_child/2. Use delete_child/2 to remove the child specification.

See start_child/2 for a description of SupRef.

If successful, the function returns ok. If there is no child specification with the specified Id, the function returns {error,not_found}.

delete_child(SupRef, Id) -> Result

Types:
- SupRef = Name | {Name,Node} | {global,Name} | pid()
- Name = Node = atom()
- Id = term()
- Result = ok | {error,Error}
- Error = running | not_found | simple_one_for_one

Tells the supervisor SupRef to delete the child specification identified by Id. The corresponding child process must not be running, use terminate_child/2 to terminate it.

See start_child/2 for a description of SupRef.

If successful, the function returns ok. If the child specification identified by Id exists but the corresponding child process is running, the function returns {error,running}. If the child specification identified by Id does not exist, the function returns {error,not_found}.

restart_child(SupRef, Id) -> Result

Types:
- SupRef = Name | {Name,Node} | {global,Name} | pid()
- Name = Node = atom()
- Id = term()
- Result = {ok,Child} | {ok,Child,Info} | {error,Error}
- Child = pid() | undefined
- Error = running | not_found | simple_one_for_one | term()

Tells the supervisor SupRef to restart a child process corresponding to the child specification identified by Id. The child specification must exist and the corresponding child process must not be running.

See start_child/2 for a description of SupRef.

If the child specification identified by Id does not exist, the function returns {error,not_found}. If the child specification exists but the corresponding process is already running, the function returns {error,running}.

If the child process start function returns {ok,Child} or {ok,Child,Info}, the pid is added to the supervisor and the function returns the same value.

If the child process start function returns ignore, the pid remains set to undefined and the function returns {ok,undefined}. 
If the child process start function returns an error tuple or an erroneous value, or if it fails, the function returns \{error,Error\} where Error is a term containing information about the error.

\[
\text{which}_{\text{children}}(\text{SupRef}) \rightarrow \left[\{\text{Id},\text{Child},\text{Type},\text{Modules}\}\right]
\]

Types:
- \text{SupRef} = \text{Name} | \{\text{Name},\text{Node}\} | \{\text{global},\text{Name}\} | \text{pid}()
- \text{Name} = \text{Node} = \text{atom}()
- \text{Id} = \text{term}() | \text{undefined}
- \text{Child} = \text{pid}() | \text{undefined}
- \text{Type} = \text{worker} | \text{supervisor}
- \text{Modules} = \{\text{Module}\} | \text{dynamic}
- \text{Module} = \text{atom}()

Returns a list with information about all child specifications and child processes belonging to the supervisor \text{SupRef}.

See \text{start}_{\text{child}}/2 for a description of \text{SupRef}.

The information given for each child specification/process is:

- \text{Id} - as defined in the child specification or \text{undefined} in the case of a simple\_one\_for\_one supervisor.
- \text{Child} - the pid of the corresponding child process, or \text{undefined} if there is no such process.
- \text{Type} - as defined in the child specification.
- \text{Modules} - as defined in the child specification.

\[
\text{check}_{\text{childspecs}}([\text{ChildSpec}]) \rightarrow \text{Result}
\]

Types:
- \text{ChildSpec} = \text{child\_spec}()
- \text{Result} = \text{ok} | \{\text{error,Error}\}
- \text{Error} = \text{term}()

This function takes a list of child specification as argument and returns \text{ok} if all of them are syntactically correct, or \{\text{error,Error}\} otherwise.

**CALLBACK FUNCTIONS**

The following functions should be exported from a \text{supervisor} callback module.
Exports

Module:init(Args) -> Result

Types:
- Args = term()
- Result = [{ok, [{RestartStrategy, M axR, M axT}, [ChildSpec]]} | ignore
- RestartStrategy = one_for_all | one_for_one | rest_for_one | simple_one_for_one
- M axR = M axT = int() >= 0
- ChildSpec = child_spec()

Whenever a supervisor is started using supervisor:start_link/2,3, this function is called by the new process to find out about restart strategy, maximum restart frequency and child specifications.

Args is the Args argument provided to the start function.

RestartStrategy is the restart strategy and MaxR and MaxT defines the maximum restart frequency of the supervisor. [ChildSpec] is a list of valid child specifications defining which child processes the supervisor should start and monitor. See the discussion about Supervision Principles above.

Note that when the restart strategy is simple_one_for_one, the list of child specifications must be a list with one child specification only. (The Id is ignored). No child process is then started during the initialization phase, but all children are assumed to be started dynamically using supervisor:start_child/2.

The function may also return ignore.

SEE ALSO

gen_event(3), gen_fsm(3), gen_server(3), sys(3)
supervisor_bridge

Erlang Module

A behaviour module for implementing a supervisor_bridge, a process which connects a subsystem not designed according to the OTP design principles to a supervision tree. The supervisor_bridge sits between a supervisor and the subsystem. It behaves like a real supervisor to its own supervisor, but has a different interface than a real supervisor to the subsystem. Refer to OTP Design Principles for more information.

A supervisor_bridge assumes the functions for starting and stopping the subsystem to be located in a callback module exporting a pre-defined set of functions.

The sys module can be used for debugging a supervisor_bridge.

Unless otherwise stated, all functions in this module will fail if the specified supervisor_bridge does not exist or if bad arguments are given.

Exports

\begin{verbatim}
start_link(Module, Args) -> Result
start_link(SupBridgeName, Module, Args) -> Result
\end{verbatim}

Types:
- SupBridgeName = \{local,Name\} | \{global,Name\}
- Name = atom()
- Module = atom()
- Args = term()
- Result = \{ok,Pid\} | ignore | \{error,Error\}
- Pid = pid()
- Error = \{already_started,Pid\} | term()

Creates a supervisor_bridge process, linked to the calling process, which calls Module:init/1 to start the subsystem. To ensure a synchronized start-up procedure, this function does not return until Module:init/1 has returned.

If SupBridgeName=\{local,Name\} the supervisor_bridge is registered locally as Name using register/2. If SupBridgeName=\{global,Name\} the supervisor_bridge is registered globally as Name using global:register_name/2. If no name is provided, the supervisor_bridge is not registered. If there already exists a process with the specified SupBridgeName the function returns \{error,[already_started,Pid]\}, where Pid is the pid of that process.

Module is the name of the callback module.

Args is an arbitrary term which is passed as the argument to Module:init/1.

If the supervisor_bridge and the subsystem are successfully started the function returns \{ok,Pid\}, where Pid is the pid of the supervisor_bridge.
If Module:init/1 returns ignore, this function returns ignore as well and the supervisor_bridge terminates with reason normal. If Module:init/1 fails or returns an error tuple or an incorrect value, this function returns {error,Term} where Term is a term with information about the error, and the supervisor_bridge terminates with reason Term.

**CALLBACK FUNCTIONS**

The following functions should be exported from a supervisor_bridge callback module.

**Exports**

**Module:init(Arg) -> Result**

Types:
- Args = term()
- Result = {ok,Pid,State} | ignore | {error,Error}
- Pid = pid()
- State = term()
- Error = term()

Whenever a supervisor_bridge is started using supervisor_bridge:start_link/2,3, this function is called by the new process to start the subsystem and initialize. Args is the Args argument provided to the start function. The function should return {ok,Pid,State} where Pid is the pid of the main process in the subsystem and State is any term. If later Pid terminates with a reason Reason, the supervisor bridge will terminate with reason Reason as well. If later the supervisor_bridge is stopped by its supervisor with reason Reason, it will call Module:terminate(Reason,State) to terminate. If something goes wrong during the initialization the function should return {error,Error} where Error is any term, or ignore.

**Module:terminate(Reason, State)**

Types:
- Reason = shutdown | term()
- State = term()

This function is called by the supervisor_bridge when it is about to terminate. It should be the opposite of Module:init/1 and stop the subsystem and do any necessary cleaning up. The return value is ignored. Reason is shutdown if the supervisor_bridge is terminated by its supervisor. If the supervisor_bridge terminates because a a linked process (apart from the main process of the subsystem) has terminated with reason Term, Reason will be Term. State is taken from the return value of Module:init/1.
SEE ALSO

supervisor(3), sys(3)
This module contains functions for sending system messages used by programs, and messages used for debugging purposes.

Functions used for implementation of processes should also understand system messages such as debugging messages and code change. These functions must be used to implement the use of system messages for a process; either directly, or through standard behaviours, such as gen_server.

The following types are used in the functions defined below:

- **Name** = pid() | atom() | {global, atom()}
- **Timeout** = int() >= 0 | infinity
- **system_event** = {in, Msg} | {in, Msg, From} | {out, Msg, To} | term()

The default timeout is 5000 ms, unless otherwise specified. The timeout defines the time period to wait for the process to respond to a request. If the process does not respond, the function evaluates `exit({timeout, {M, F, A}})`.

The functions make reference to a debug structure. The debug structure is a list of `dbg_opt()`. `dbg_opt()` is an internal data type used by the `handle_system_msg/6` function. No debugging is performed if it is an empty list.

### System Messages

Processes which are not implemented as one of the standard behaviours must still understand system messages. There are three different messages which must be understood:

- **Plain system messages.** These are received as `{system, From, Msg}`. The content and meaning of this message are not interpreted by the receiving process module. When a system message has been received, the function `sys:handle_system_msg/6` is called in order to handle the request.

- **Shutdown messages.** If the process traps exits, it must be able to handle a shut-down request from its parent, the supervisor. The message `{EXIT, Parent, Reason}` from the parent is an order to terminate. The process must terminate when this message is received, normally with the same Reason as Parent.
There is one more message which the process must understand if the modules used to implement the process change dynamically during runtime. An example of such a process is the `gen_event` processes. This message is `/CU get_modules, From`. The reply to this message is `From ! {modules, Modules}`, where `Modules` is a list of the currently active modules in the process. This message is used by the release handler to find which processes execute a certain module. The process may at a later time be suspended and ordered to perform a code change for one of its modules.

**System Events**

When debugging a process with the functions of this module, the process generates `system_events` which are then treated in the debug function. For example, `trace` formats the system events to the tty.

There are three predefined system events which are used when a process receives or sends a message. The process can also define its own system events. It is always up to the process itself to format these events.

**Exports**

```
log(Name,Flag)
log(Name,Flag,Timeout) -> ok | {ok, [system_event()]}  
  Types:
  • Flag = true | {true, N} | false | get | print
  • N = integer() > 0
  Turns the logging of system events On or Off. If On, a maximum of N events are kept in the debug structure (the default is 10). If Flag is get, a list of all logged events is returned. If Flag is print, the logged events are printed to standard io. The events are formatted with a function that is defined by the process that generated the event (with a call to `sys:handle_debug/4`).

log_to_file(Name,Flag)
log_to_file(Name,Flag,Timeout) -> ok | {error, open_file}  
  Types:
  • Flag = FileName | false
  • FileName = string()
  Enables or disables the logging of all system events in textual format to the file. The events are formatted with a function that is defined by the process that generated the event (with a call to `sys:handle_debug/4`).

statistics(Name,Flag)
statistics(Name,Flag,Timeout) -> ok | {ok, Statistics}  
  Types:
  • Flag = true | false | get
```
Statistics = [
    {start_time, {Date1, Time1}},
    {current_time, {Date, Time2}},
    {reductions, integer()},
    {messages_in, integer()},
    {messages_out, integer()}]

Date1 = Date2 = Year, Month, Day
Time1 = Time2 = Hour, Min, Sec

Enables or disables the collection of statistics. If Flag is get, the statistical collection is returned.

trace(Name, Flag)
trace(Name, Flag, Timeout) -> void()

Types:
- Flag = boolean()

Prints all system events on standard io. The events are formatted with a function that is defined by the process that generated the event (with a call to sys:handle_debug/4).

no_debug(Name)
no_debug(Name, Timeout) -> void()

Turns off all debugging for the process. This includes functions that have been installed explicitly with the install function, for example triggers.

suspend(Name)
suspend(Name, Timeout) -> void()

Suspends the process. When the process is suspended, it will only respond to other system messages, but not other messages.

resume(Name)
resume(Name, Timeout) -> void()

Resumes a suspended process.

change_code(Name, Module, OldVsn, Extra)
change_code(Name, Module, OldVsn, Extra, Timeout) -> ok | {error, Reason}

Types:
- OldVsn = undefined | term()
- Module = atom()
- Extra = term()

Tells the process to change code. The process must be suspended to handle this message. The Extra argument is reserved for each process to use as its own. The function Mod:system_code_change/4 is called. OldVsn is the old version of the Module.

get_status(Name)
get_status(Name, Timeout) -> {status, Pid, {module, Mod}, [PDict, SysState, Parent, Dbg, Misc]}

Types:
- PDict = [{Key, Value}]
- SysState = running | suspended
- Parent = pid()
*DBG = \[dbg_opt()\]
*Misc = term()

Gets the status of the process.

\[
\text{install(Name, } \{\text{Func, FuncState}\}\) \\
\text{install(Name, } \{\text{Func, FuncState}\}, \text{Timeout})
\]

Types:
* Func = dbg\_fun()
* dbg\_fun() = fun(FuncState, Event, ProcState) \rightarrow \text{done} \mid \text{NewFuncState}
* FuncState = term()
* Event = system\_event()
* ProcState = term()
* NewFuncState = term()

This function makes it possible to install other debug functions than the ones defined above. An example of such a function is a trigger, a function that waits for some special event and performs some action when the event is generated. This could, for example, be turning on low level tracing.

Func is called whenever a system event is generated. This function should return \text{done}, or a new func state. In the first case, the function is removed. It is removed if the function fails.

\[
\text{remove(Name, Func)} \\
\text{remove(Name, Func, Timeout)} \rightarrow \text{void()}
\]

Types:
* Func = dbg\_fun()

Removes a previously installed debug function from the process. Func must be the same as previously installed.

### Process Implementation Functions

The following functions are used when implementing a special process. This is an ordinary process which does not use a standard behaviour, but a process which understands the standard system messages.
Exports

debug_options(Options) -> [dbg_opt()]

Types:
- Options = [Opt]
- Opt = trace | log | statistics | {log_to_file, FileName} | {install, {Func, FuncState}}
- Func = dbg_fun()
- FuncState = term()

This function can be used by a process that initiates a debug structure from a list of options. The values of the Opt argument are the same as the corresponding functions.

get_debug(Item, Debug, Default) -> term()

Types:
- Item = log | statistics
- Debug = [dbg_opt()]
- Default = term()

This function gets the data associated with a debug option. Default is returned if the Item is not found. Can be used by the process to retrieve debug data for printing before it terminates.

handle_debug([dbg_opt()], FormFunc, Extra, Event) -> [dbg_opt()]

Types:
- FormFunc = dbg_fun()
- Extra = term()
- Event = system_event()

This function is called by a process when it generates a system event. FormFunc is a formatting function which is called as FormFunc(Device, Event, Extra) in order to print the events, which is necessary if tracing is activated. Extra is any extra information which the process needs in the format function, for example the name of the process.

handle_system_msg(Msg, From, Parent, Module, Debug, Misc)

Types:
- Msg = term()
- From = pid()
- Parent = pid()
- Module = atom()
- Debug = [dbg_opt()]
- Misc = term()
This function is used by a process module that wishes to take care of system messages. The process receives a \{system, From, Msg\} message and passes the \textit{Msg} and \textit{From} to this function.

This function never returns. It calls the function \texttt{Module:system:continue(Parent, NDebug, Misc)} where the process continues the execution, or \texttt{Module:system:terminate(Reason, Parent, Debug, Misc)} if the process should terminate. The Module must export \texttt{system:continue/3}, \texttt{system:terminate/4}, and \texttt{system:code:change/4} (see below).

The Misc argument can be used to save internal data in a process, for example its state. It is sent to \texttt{Module:system:continue/3} or \texttt{Module:system:terminate/4}.

\texttt{print_log(Debug) \rightarrow \texttt{void()}}

\textbf{Types:}
- \texttt{Debug = \{dbg_opt\}}

Prints the logged system events in the debug structure using \texttt{FormFunc} as defined when the event was generated by a call to \texttt{handle:debug/4}.

\texttt{Mod:system:continue(Parent, Debug, Misc)}

\textbf{Types:}
- \texttt{Parent = pid()}
- \texttt{Debug = \{dbg_opt\}}
- \texttt{Misc = term()}

This function is called from \texttt{sys:handle:system:msg/6} when the process should continue its execution (for example after it has been suspended). This function never returns.

\texttt{Mod:system:terminate(Reason, Parent, Debug, Misc)}

\textbf{Types:}
- \texttt{Reason = term()}
- \texttt{Parent = pid()}
- \texttt{Debug = \{dbg_opt\}}
- \texttt{Misc = term()}

This function is called from \texttt{sys:handle:system:msg/6} when the process should terminate. For example, this function is called when the process is suspended and its parent orders shut-down. It gives the process a chance to do a clean-up. This function never returns.

\texttt{Mod:system:code:change(Misc, Module, OldVsn, Extra) \rightarrow \{ok, NMisc\}}

\textbf{Types:}
- \texttt{Misc = term()}
- \texttt{OldVsn = undefined | term()}
- \texttt{Module = atom()}
- \texttt{Extra = term()}
- \texttt{NMisc = term()}
Called from `sys:handle_system_msg/6` when the process should perform a code change. The code change is used when the internal data structure has changed. This function converts the `Misc` argument to the new data structure. `OldVsn` is the `vsn` attribute of the old version of the `Module`. If no such attribute was defined, the atom `undefined` is sent.
timer
Erlang Module

This module provides useful functions related to time. Unless otherwise stated, time is always measured in milliseconds. All timer functions return immediately, regardless of work carried out by another process.

Successful evaluations of the timer functions yield return values containing a timer reference, denoted TRef below. By using cancel/1, the returned reference can be used to cancel any requested action. A TRef is an Erlang term, the contents of which must not be altered.

The timeouts are not exact, but should be at least as long as requested.

Exports

start() -> ok

Starts the timer server. Normally, the server does not need to be started explicitly. It is started dynamically if it is needed. This is useful during development, but in a target system the server should be started explicitly. Use configuration parameters for kernel for this.

apply_after(Time, Module, Function, Arguments) -> {ok, TRef} | {error, Reason}

Types:
• Time = integer() in Milliseconds
• Module = Function = atom()
• Arguments = [term()]

Evaluates apply(M, F, A) after Time amount of time has elapsed. Returns {ok, TRef}, or {error, Reason}.

send_after(Time, Pid, Message) -> {ok, TRef} | {error, Reason}

send_after(Time, Message) -> {ok, TRef} | {error, Reason}

Types:
• Time = integer() in Milliseconds
• Pid = pid() | atom()
• Message = term()
• Result = {ok, TRef} | {error, Reason}

send_after/3 Evaluates Pid ! Message after Time amount of time has elapsed. (Pid can also be an atom of a registered name.) Returns {ok, TRef}, or {error, Reason}. 
send_after/2 Same as send_after(Time, self(), Message).

exit_after(Time, Pid, Reason1) -> {ok, TRef} | {error,Reason2}
exit_after(Time, Reason1) -> {ok, TRef} | {error,Reason2}
kill_after(Time, Pid) -> {ok, TRef} | {error,Reason2}
kscript_after(Time) -> {ok, TRef} | {error,Reason2}

Types:
- Time = integer() in milliseconds
- Pid = pid() | atom()
- Reason1 = Reason2 = term()

exit_after/3 Send an exit signal with reason Reason1 to Pid Pid. Returns {ok, TRef}, or {error, Reason2}.
exit_after/2 Same as exit_after(Time, self(), Reason1).
kscript_after/2 Same as exit_after(Time, Pid, kill).
kscript_after/1 Same as exit_after(Time, self(), kill).

apply_interval(Time, Module, Function, Arguments) -> {ok, TRef} | {error, Reason}

Types:
- Time = integer() in milliseconds
- Module = Function = atom()
- Arguments = [term()]

Evaluates apply(Module, Function, Arguments) repeatedly at intervals of Time. Returns {ok, TRef}, or {error, Reason}.

send_interval(Time, Pid, Message) -> {ok, TRef} | {error, Reason}
send_interval(Time, Message) -> {ok, TRef} | {error, Reason}

Types:
- Time = integer() in milliseconds
- Pid = pid() | atom()
- Message = term()
- Reason = term()

send_interval/3 Evaluates Pid ! Message repeatedly after Time amount of time has elapsed. (Pid can also be an atom of a registered name.) Returns {ok, TRef} or {error, Reason}.
send_interval/2 Same as send_interval(Time, self(), Message).

cancel(TRef) -> {ok, cancel} | {error, Reason}

Cancels a previously requested timeout. TRef is a unique timer reference returned by the timer function in question. Returns {ok, cancel}, or {error, Reason} when TRef is not a timer reference.

sleep(Time) -> ok
Timer STDLIB Reference Manual

Types:
- **Time** = integer() in milliseconds

Suspends the process calling this function for Time amount of milliseconds and then returns **ok**. Naturally, this function does not return immediately.

\[
\text{tc(Module, Function, Arguments)} \rightarrow \{\text{Time, Value}\}
\]

Types:
- **Module** = Function = atom()
- **Arguments** = [term()]
- **Time** = integer() in microseconds
- **Value** = term()

Evaluates apply(Module, Function, Arguments) and measures the elapsed real time. Returns \{Time, Value\}, where Time is the elapsed real time in microseconds, and Value is what is returned from the apply.

\[
\text{seconds(Seconds)} \rightarrow \text{Milliseconds}
\]

Returns the number of milliseconds in Seconds.

\[
\text{minutes(Minutes)} \rightarrow \text{Milliseconds}
\]

Return the number of milliseconds in Minutes.

\[
\text{hours(Hours)} \rightarrow \text{Milliseconds}
\]

Returns the number of milliseconds in Hours.

\[
\text{hms(Hours, Minutes, Seconds)} \rightarrow \text{Milliseconds}
\]

Returns the number of milliseconds in Hours + Minutes + Seconds.

**Examples**

This example illustrates how to print out “Hello World!” in 5 seconds:

\[
1> \text{timer:apply_after(5000, io, format, ["~nHello World!~n", []]).}
\]

{ok, TRef}

Hello World!

2>

The following coding example illustrates a process which performs a certain action and if this action is not completed within a certain limit, then the process is killed.

\[
\text{Pid = spawn(mod, fun, [foo, bar]),}
\]

%% If pid is not finished in 10 seconds, kill him

{ok, R} = timer:kill_after(timer:seconds(10), Pid),

...

%% We change our mind...

\text{timer:cancel(R),}

...
WARNING

A timer can always be removed by calling `cancel/1`.

An interval timer, i.e. a timer created by evaluating any of the functions `apply_interval/4`, `send_interval/3`, and `send_interval/2`, is linked to the process towards which the timer performs its task.

A one-shot timer, i.e. a timer created by evaluating any of the functions `apply_after/4`, `send_after/3`, `send_after/2`, `exit_after/3`, `exit_after/2`, `kill_after/2`, and `kill_after/1` is not linked to any process. Hence, such a timer is removed only when it reaches its timeout, or if it is explicitly removed by a call to `cancel/1`. 
win32reg

Erlang Module

win32reg provides read and write access to the registry on Windows. It is essentially a port driver wrapped around the Win32 API calls for accessing the registry. The registry is a hierarchical database, used to store various system and software information in Windows. It is available in Windows 95 and Windows NT. It contains installation data, and is updated by installers and system programs. The Erlang installer updates the registry by adding data that Erlang needs.

The registry contains keys and values. Keys are like the directories in a file system, they form a hierarchy. Values are like files, they have a name and a value, and also a type.

Paths to keys are left to right, with sub-keys to the right and backslash between keys. (Remember that backslashes must be doubled in Erlang strings.) Case is preserved but not significant. Example:

"\hkey\local\machine\software\Ericsson\Erlang\5.0" is the key for the installation data for the latest Erlang release.

There are six entry points in the Windows registry, top level keys. They can be abbreviated in the win32reg module as:

<table>
<thead>
<tr>
<th>Abbrev.</th>
<th>Registry key</th>
</tr>
</thead>
<tbody>
<tr>
<td>hkcr</td>
<td>HKEY_CLASSES_ROOT</td>
</tr>
<tr>
<td>current_user</td>
<td>HKEY_CURRENT_USER</td>
</tr>
<tr>
<td>hkcu</td>
<td>HKEY_CURRENT_USER</td>
</tr>
<tr>
<td>local_machine</td>
<td>HKEY_LOCAL_MACHINE</td>
</tr>
<tr>
<td>hklm</td>
<td>HKEY_LOCAL_MACHINE</td>
</tr>
<tr>
<td>users</td>
<td>HKEY_USERS</td>
</tr>
<tr>
<td>hku</td>
<td>HKEY_USERS</td>
</tr>
<tr>
<td>current_config</td>
<td>HKEY_CURRENT_CONFIG</td>
</tr>
<tr>
<td>hkc</td>
<td>HKEY_CURRENT_CONFIG</td>
</tr>
<tr>
<td>dyn_data</td>
<td>HKEY_DYN_DATA</td>
</tr>
<tr>
<td>hkdd</td>
<td>HKEY_DYN_DATA</td>
</tr>
</tbody>
</table>

The key above could be written as "\hklm\software\ericsson\erlang\5.0".

The win32reg module uses a current key. It works much like the current directory. From the current key, values can be fetched, sub-keys can be listed, and so on.

Under a key, any number of named values can be stored. They have name, and types, and data.

Currently, the win32reg module supports storing only the following types: REG_DWORD, which is an integer, REG_SZ which is a string and REG_BINARY which is a binary. Other types can be read, and will be returned as binaries.

There is also a “default” value, which has the empty string as name. It is read and written with the atom default instead of the name.
Some registry values are stored as strings with references to environment variables, e.g. "%SystemRoot%Windows". SystemRoot is an environment variable, and should be replaced with its value. A function expand/1 is provided, so that environment variables surrounded in % can be expanded to their values.

For additional information on the Windows registry consult the Win32 Programmer’s Reference.

Exports

change_key(RegHandle, Key) -> ReturnValue
Types:
- RegHandle = term()
- Key = string()
Changes the current key to another key. Works like cd. The key can be specified as a relative path or as an absolute path, starting with \\.

change_key_create(RegHandle, Key) -> ReturnValue
Types:
- RegHandle = term()
- Key = string()
Creates a key, or just changes to it, if it is already there. Works like a combination of mkdir and cd. Calls the Win32 API function RegCreateKeyEx(). The registry must have been opened in write-mode.

close(RegHandle) -> ReturnValue
Types:
- RegHandle = term()
Closes the registry. After that, the RegHandle cannot be used.

current_key(RegHandle) -> ReturnValue
Types:
- RegHandle = term()
- ReturnValue = {ok, string()}
Returns the path to the current key. This is the equivalent of pwd. Note that the current key is stored in the driver, and might be invalid (e.g. if the key has been removed).

delete_key(RegHandle) -> ReturnValue
Types:
- RegHandle = term()
- ReturnValue = ok | {error, ErrorId}
Deletes the current key, if it is valid. Calls the Win32 API function RegDeleteKey(). Note that this call does not change the current key, (unlike change_key/2.) This means that after the call, the current key is invalid.

delete_value(RegHandle, Name) -> ReturnValue

Types:
- RegHandle = term()
- ReturnValue = ok | {error, ErrorId}

Deletes a named value on the current key. The atom default is used for the the default value.

The registry must have been opened in write-mode.

expand(String) -> ExpandedString

Types:
- String = string()
- ExpandedString = string()

Expands a string containing environment variables between percent characters. Anything between two % is taken for a environment variable, and is replaced by the value. Two consecutive % is replaced by one %.

A variable name that is not in the environment, will result in an error.

format_error(ErrorId) -> ErrorString

Types:
- ErrorId = atom()
- ErrorString = string()

Convert an POSIX errorcode to a string (by calling erl_posix_msg:message).

open(OpenModeList) -> ReturnValue

Types:
- OpenModeList = [OpenMode]
- OpenMode = read | write

Opens the registry for reading or writing. The current key will be the root (HKEY_CLASSES_ROOT). The read flag in the mode list can be omitted. Use change_key/2 with an absolute path after open.

set_value(RegHandle, Name, Value) -> ReturnValue

Types:
- Name = string() | default
- Value = string() | integer() | binary()
Sets the named (or default) value to value. Calls the Win32 API function 
RegSetValEx(). The value can be of three types, and the corresponding registry type 
will be used. Currently the types supported are: REG_DWORD for integers, REG_SZ for 
strings and REG_BINARY for binaries. Other types cannot currently be added or changed. 
The registry must have been opened in write-mode.

sub_keys(RegHandle) -> ReturnValue
   Types:
   • ReturnValue = {ok, SubKeys} | {error, ErrorId}
   • SubKeys = [SubKey]
   • SubKey = string()
   Returns a list of subkeys to the current key. Calls the Win32 API function 
EnumRegKeysEx().
   Avoid calling this on the root keys, it can be slow.

value(RegHandle, Name) -> ReturnValue
   Types:
   • Name = string() | default
   • ReturnValue = {ok, Value}
   • Value = string() | integer() | binary()
   Retrieves the named value (or default) on the current key. Registry values of type 
REG_SZ, are returned as strings. Type REG_DWORD values are returned as integers. All 
other types are returned as binaries.

values(RegHandle) -> ReturnValue
   Types:
   • ReturnValue = {ok, ValuePairs}
   • ValuePairs = [ValuePair]
   • ValuePair = {Name, Value}
   • Name = string | default
   • Value = string() | integer() | binary()
   Retrieves a list of all values on the current key. The values have types corresponding to 
the registry types, see value. Calls the Win32 API function EnumRegValuesEx().
