Erlang ODBC User's Guide

The Erlang ODBC Application provides an interface for accessing relational SQL-databases from Erlang.

1.1 Introduction

1.1.1 Purpose

The purpose of the Erlang ODBC application is to provide the programmer with an ODBC interface that has a Erlang/OTP touch and feel. So that the programmer may concentrate on solving his/her actual problem instead of struggling with pointers and memory allocation which is not very relevant for Erlang. This user guide will give you some information about technical issues and provide some examples of how to use the Erlang ODBC interface.

1.1.2 Prerequisites

It is assumed that the reader is familiar with the Erlang programming language, concepts of OTP and has a basic understanding of relational databases and SQL.

1.1.3 About ODBC

Open Database Connectivity (ODBC) is a Microsoft standard for accessing relational databases that has become widely used. The ODBC standard provides a c-level application programming interface (API) for database access. It uses Structured Query Language (SQL) as its database access language.

1.1.4 About the Erlang ODBC application

Provides an Erlang interface to communicate with relational SQL-databases. It is built on top of Microsoft's ODBC interface and therefore requires that you have an ODBC driver to the database that you want to connect to. The Erlang ODBC application is designed using the version 3.0 of the ODBC-standard, however using the option \{scrollable\_cursors, off\} for a connection has been known to make it work for at least some 2.X drivers.
1.2 Getting started

1.2.1 Setting things up

As the Erlang ODBC application is dependent on third party products there are a few administrative things that needs to be done before you can get things up and running.

- The first thing you need to do, is to make sure you have an ODBC driver installed for the database that you want to access. Both the client machine where you plan to run your erlang node and the server machine running the database needs the ODBC driver. (In some cases the client and the server may be the same machine).
- Secondly you might need to set environment variables and paths to appropriate values. This may differ a lot between different os's, databases and ODBC drivers. This is a configuration problem related to the third party product and hence we can not give you a standard solution in this guide.
- The Erlang ODBC application consists of both Erlang and C code. The C code is delivered as a precompiled executable for windows and solaris. If you for any reason need to recompile the C code or if you are running some other os and want to compile the code there is a include makefile to help you do so.

Note:
The Erlang ODBC application should run on all Unix dialects including Linux, Windows 2000, Windows XP and NT. But currently it is only tested for Solaris, Windows 2000, Windows XP and NT.

1.2.2 Compiling on Windows

On windows compilers are often distributed in some development environment such as Visual C++, that is what we use to compile the C code for windows.

If you need to compile the C code open a command prompt. Assume that Erlang/OTP is installed at “c:\Program Files\erl<erlang-version>”. Change to the directory “c:\Program Files\erl<erlang-version>\lib\odbc<odbc-version>\c\src” directory. Here you will find a Makefile. There are three variables in this makefile that you may want to override.

- ODBCLIBS - Path to the ODBC library.
- ODBCINCLUDE - Path to the ODBC header files
- EIROOT - Path to the root directory of the Erlang application erl\interface.

An example of how the make command might look:

```
nmake EIROOT="..\.\.\lib\erl_interface-3.3.0"
```
1.2.3 Compiling on Unix

The preferred compiler is gcc version 2.7.2 or higher. Assume that the Erlang/OTP is installed in /usr/local/erlang then the C code is located in the /usr/local/erlang/lib/odbc-<odbc-version>/c_src directory. In the C code directory you will find a Makefile. There are three variables in this make file that you may want to override.

- **ODBCROOT** - Path to the root directory of the ODBC installation.
- **ODBCLIBS** - Path to the ODBC library.
- **EIROOT** - Root directory of the Erlang application erl_interface.

An example of how the make command might look:

```
gmake EIROOT="../../../lib/erl_interface-3.3.0"
```

1.2.4 Using the Erlang API

The following dialog within the Erlang shell illustrates the functionality of the Erlang ODBC interface. The table used in the example does not have any relevance to anything that exist in reality, it is just a simple example. The example was created using sqlserver 7.0 with servicepack 1 as database and the ODBC driver for sqlserver with version 2000.80.194.00.

```
1 > application:start(odbc).
   ok

2 > {ok, Ref} = odbc:connect("DSN=sql-server;UID=aladin;PWD=sesame", []).
   {ok,<0.342.0>}

3 > odbc:sql_query(Ref, "CREATE TABLE EMPLOYEE (NR integer, FIRSTNAME char varying(20), LASTNAME char varying(20), GENDER char(1), PRIMARY KEY(NR))").
   {updated,undefined}

4 > odbc:sql_query(Ref, "INSERT INTO EMPLOYEE VALUES(1, 'Jane', 'Doe', 'F')").
   {updated,1}

5 > odbc:describe_table(Ref, "EMPLOYEE").
   {ok, [{"NR", sql_integer},
          {"FIRSTNAME", {sql_varchar, 20}},
          {"LASTNAME", {sql_varchar, 20}},
          {"GENDER", {sql_char, 1}}]}
```

Erlang ODBC application
Use a parameterized query to insert many rows in one go.

```
6 > odbc:param_query(Ref,"INSERT INTO EMPLOYEE (NR, FIRSTNAME, "
"LASTNAME, GENDER) VALUES(?, ?, ?, ?)",
  [{sql_integer,[2,3,4,5,6,7,8]},
   {sql_vchar, 20},
   ["John", "Monica", "Ross", "Rachel",
   "Piper", "Prue", "Louise"],
   {sql_vchar, 20},
   ["Doe", "Geller", "Geller", "Green",
   "Halliwell", "Halliwell", "Lane"],
   {sql_char, 1}, ["M","F","M","F","F","F","F"]}).
{updated, 7}
```

Fetch all data in the table employee

```
7> odbc:sql_query(Ref, "SELECT * FROM EMPLOYEE").
{selected,["NR","FIRSTNAME","LASTNAME","GENDER"],
  [{1,"Jane","Doe","F"},
   {2,"John","Doe","M"},
   {3,"Monica","Geller","F"},
   {4,"Ross","Geller","M"},
   {5,"Rachel","Green","F"},
   {6,"Piper","Halliwell","F"},
   {7,"Prue","Halliwell","F"},
   {8,"Louise","Lane","F"}]}
```

Associate a result set containing the whole table EMPLOYEE to the connection. The number of rows in the result set is returned.

```
8 > odbc:select_count(Ref, "SELECT * FROM EMPLOYEE").
{ok,8}
```

You can always traverse the result set sequential by using next

```
9 > odbc:next(Ref).
{selected,["NR","FIRSTNAME","LASTNAME","GENDER"],
  [{1,"Jane","Doe","F"}]
10 > odbc:next(Ref).
{selected,["NR","FIRSTNAME","LASTNAME","GENDER"],
  [{2,"John","Doe","M"}]
```

If your driver supports scrollable cursors you have a little more freedom, and can do things like this.

```
11 > odbc:last(Ref).
{selected,["NR","FIRSTNAME","LASTNAME","GENDER"],
  [{8,"Louise","Lane","F"}]
12 > odbc:prev(Ref).
{selected,["NR","FIRSTNAME","LASTNAME","GENDER"],
  [{7,"Prue","Halliwell","F"}]
13 > odbc:first(Ref).
{selected,["NR","FIRSTNAME","LASTNAME","GENDER"],
  [{1,"Jane","Doe","F"}]
```
14 > odbc:next(Ref).
   {selected,["NR","FIRSTNAME","LASTNAME","GENDER"],[{2,"John","Doe","M"}]}

Fetch the fields FIRSTNAME and NR for all female employees

15 > odbc:sql_query(Ref, "SELECT FIRSTNAME, NR FROM EMPLOYEE WHERE GENDER = 'F'").
   {selected,["FIRSTNAME","NR"],
    [{"Jane",1},
     {"Monica",3},
     {"Rachel",5},
     {"Piper",6},
     {"Prue",7},
     {"Louise",8}]
   }

Fetch the fields FIRSTNAME and NR for all female employees and sort them on the field FIRSTNAME .

16 > odbc:sql_query(Ref, "SELECT FIRSTNAME, NR FROM EMPLOYEE WHERE GENDER = 'F'
ORDER BY FIRSTNAME").
   {selected,["FIRSTNAME","NR"],
    [{"Jane",1},
     {"Louise",8},
     {"Monica",3},
     {"Piper",6},
     {"Prue",7},
     {"Rachel",5}]
   }

Associate a result set that contains the fields FIRSTNAME and NR for all female employees to the connection. The number of rows in the result set is returned.

17 > odbc:select_count(Ref, "SELECT FIRSTNAME, NR FROM EMPLOYEE WHERE GENDER = 'F'").
   {ok,6}

A few more ways of retrieving parts of the result set when the driver supports scrollable cursors. Note that next will work even without support for scrollable cursors.

18 > odbc:select(Ref, {relative, 2}, 3).
   {selected,["FIRSTNAME","NR"],[{"Monica",3},"Rachel",5,"Piper",6]}

19 > odbc:select(Ref, next, 2).
   {selected,["FIRSTNAME","NR"],[{"Prue",7},"Louise",8]}

20 > odbc:select(Ref, {absolute, 1}, 2).
   {selected,["FIRSTNAME","NR"],[{"Jane",1}"Monica",3]}

21 > odbc:select(Ref, next, 2).
   {selected,["FIRSTNAME","NR"],[{"Rachel",5}"Piper",6]}

22 > odbc:select(Ref, {absolute, 1}, 4).
   {selected,["FIRSTNAME","NR"],
    [{"Jane",1},"Monica",3,"Rachel",5,"Piper",6]}

Erlang ODBC application
Select, using a parameterized query.

```
23 > odbc:param_query(Ref, "SELECT * FROM EMPLOYEE WHERE GENDER=?",
    [[{sql_char, 1}, ["M"]]]).
    {selected, ["NR", "FIRSTNAME", "LASTNAME", "GENDER"],
```

Delete the table EMPLOYEE.

```
24 > odbc:sql_query(Ref, "DROP TABLE EMPLOYEE").
    {updated, undefined}
```

Shut down the connection.

```
25 > odbc:disconnect(Ref).
    ok
```

Shut down the application.

```
26 > application:stop(odbc).
    =INFO REPORT==== 7-Jan-2004::17:00:59 ===
    application: odbc
    exited: stopped
    type: temporary
    ok
```

### 1.3 Databases

#### 1.3.1 Databases

If you need to access a relational database such as sqlserver, mysql, postgres, oracle, cybase etc. from your erlang application using the Erlang ODBC interface is the way to go about it.

The Erlang ODBC application should work for any relational database that has an ODBC driver. But currently it is only tested for sqlserver and oracle.
1.3.2 Database independence

The Erlang ODBC interface is in principal database independent, i.e., an erlang program using the interface could be run without changes towards different databases. But as SQL is used it is alas possible to write database dependent programs. Even though SQL is an ANSI-standard meant to be database independent, different databases have proprietary extensions to SQL defining their own data types. If you keep to the ANSI data types you will minimize the problem. But unfortunately there is no guarantee that all databases actually treat the ANSI data types equivalently. For instance an installation of Oracle Enterprise release 8.0.5.0.0 for unix will accept that you create a table column with the ANSI data type `integer`, but when retriving values from this column the driver reports that it is of type `SQL_DECIMAL(0, 38)` and not `SQL_INTEGER` as you may have expected.

Another obstacle is that some drivers do not support scrollable cursors which has the effect that the only way to traverse the result set is sequentially, with next, from the first row to the last, and once you pass a row you can not go back. This means that some functions in the interface will not work together with certain drivers. A similar problem is that not all drivers support “row count” for select queries, hence resulting in that the function `select_count([3,4])` will return `{ok, undefined}` instead of `{ok, NrRows}` where NrRows is the number of rows in the result set.

1.3.3 Data types

The following is a list of the ANSI data types. For details turn to the ANSI standard documentation. Usage of other data types is of course possible, but you should be aware that this makes your application dependent on the database you are using at the moment.

- `CHARACTER (size), CHAR (size)`
- `NUMERIC (precision, scale), DECIMAL (precision, scale), DEC (precision, scale)` precision - total number of digits, scale - total number of decimal places
- `INTEGER, INT, SMALLINT`
- `FLOAT (precision)`
- `REAL`
- `DOUBLE PRECISION`
- `CHARACTER VARYING (size), CHAR VARYING (size)`

When inputing data using `sql_query([2,3])` the values will always be in string format as they are part of an SQL-query. Example:

```
odbc:sql_query(Ref, "INSERT INTO TEST VALUES(1, 2, 3)").
```

**Note:**

Note that when the value of the data to input is a string, it has to be quoted with ''. Example:

```
odbc:sql_query(Ref, "INSERT INTO EMPLOYEE VALUES(1, 'Jane', 'Doe', 'F')").
```

You may also input data using `param_query([3,4])` and then the input data will have the Erlang type corresponding to the ODBC type of the column. See ODBC to Erlang mapping.
When selecting data from a table, all data types are returned from the database to the ODBC driver as an ODBC data type. The tables below show the mapping between those data types and what is returned by the Erlang API.

<table>
<thead>
<tr>
<th>ODBC Data Type</th>
<th>Erlang Data Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>SQL_CHAR(size)</td>
<td>String</td>
</tr>
<tr>
<td>SQL_NUMERIC(p,s) when (p &gt;= 0 and p &lt;= 9 and s == 0)</td>
<td>Integer</td>
</tr>
<tr>
<td>SQL_NUMERIC(p,s) when (p &gt;= 10 and p &lt;= 15 and s == 0) or (s &lt;= 15 and s &gt; 0)</td>
<td>Float</td>
</tr>
<tr>
<td>SQL_NUMERIC(p,s) when p &gt;= 16</td>
<td>String</td>
</tr>
<tr>
<td>SQL_DECIMAL(p,s) when (p &gt;= 0 and p &lt;= 9 and s == 0)</td>
<td>Integer</td>
</tr>
<tr>
<td>SQL_DECIMAL(p,s) when (p &gt;= 10 and p &lt;= 15 and s == 0) or (s &lt;= 15 and s &gt; 0)</td>
<td>Float</td>
</tr>
<tr>
<td>SQL_DECIMAL(p,s) when p &gt;= 16</td>
<td>String</td>
</tr>
<tr>
<td>SQL_INTEGER</td>
<td>Integer</td>
</tr>
<tr>
<td>SQL_SMALLINT</td>
<td>Integer</td>
</tr>
<tr>
<td>SQL_FLOAT</td>
<td>Float</td>
</tr>
<tr>
<td>SQL_REAL</td>
<td>Float</td>
</tr>
<tr>
<td>SQL_DOUBLE</td>
<td>Float</td>
</tr>
<tr>
<td>SQL_VARCHAR(size)</td>
<td>String</td>
</tr>
</tbody>
</table>

Table 1.1: Mapping of ODBC data types to the Erlang data types returned to the Erlang application.

<table>
<thead>
<tr>
<th>ODBC Data Type</th>
<th>Erlang Data Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>SQL_DATE</td>
<td>String</td>
</tr>
<tr>
<td>SQL_TIME</td>
<td>String</td>
</tr>
<tr>
<td>SQL_TIMESTAMP</td>
<td>String</td>
</tr>
<tr>
<td>SQL_LONGVARCHAR</td>
<td>String</td>
</tr>
<tr>
<td>SQL_BINARY</td>
<td>String</td>
</tr>
<tr>
<td>SQL_VARBINARY</td>
<td>String</td>
</tr>
<tr>
<td>SQL_LONGVARBINARY</td>
<td>String</td>
</tr>
<tr>
<td>SQL_TINYINT</td>
<td>Integer</td>
</tr>
<tr>
<td>SQL_BIT</td>
<td>Boolean</td>
</tr>
</tbody>
</table>

Table 1.2: Mapping of extended ODBC data types to the Erlang data types returned to the Erlang application.

**Note:**
To find out which data types will be returned for the columns in a table use the function `describe_table/[2,3]` [page 18]
1.3.4 Batch handling

Grouping of SQL queries can be desirable in order to reduce network traffic. Another benefit can be that the data source sometimes can optimize execution of a batch of SQL queries.

Explicit batches an procedures described below will result in multiple results being returned from sql_query/[2,3]. while with parameterized queries only one result will be returned from param_query/[2,3].

Explicit batches

The most basic form of a batch is created by semicolons separated SQL queries, for example:

"SELECT * FROM FOO; SELECT * FROM BAR" or
"INSERT INTO FOO VALUES(1,'bar'); SELECT * FROM FOO"

Procedures

Different databases may also support creating of procedures that contains more than one SQL query. For example, the following SQL Server-specific statement creates a procedure that returns a result set containing information about employees that work at the department and and a result set listing the customers of that department.

```sql
CREATE PROCEDURE DepartmentInfo (@DepartmentID INT) AS
    SELECT * FROM Employee WHERE department = @DepartmentID
    SELECT * FROM Customers WHERE department = @DepartmentID
```

Parameterized queries

To effectively perform a batch of similar queries, you can use parameterized queries. This means that you in your SQL query string will mark the places that usually would contain values with question marks and then provide lists of values for each parameter. For instance you can use this to insert multiple rows into the EMPLOYEE table while executing only a single SQL statement, for example code see "Using the Erlang API" [page 4] section in the “Getting Started” chapter.

1.4 Error handling

1.4.1 Strategy

On a conceptual level starting a database connection using the Erlang ODBC API is a basic client server application. The client process uses the API to start and communicate with the server process that manages the connection. The strategy of the Erlang ODBC application is that programming faults in the application itself will cause the connection process to terminate abnormally. (When a process terminates abnormally its supervisor will log relevant error reports.) Calls to API functions during or after termination of the connection process will return {error, connection_closed}. Contextual errors on the other hand will not terminate the connection it will only return {error, Reason} to the client, where Reason may be any erlang term.
Chapter 1: Erlang ODBC User's Guide

Clients

The connection is associated with the process that created it and can only be accessed through it. The reason for this is to preserve the semantics of result sets and transactions when select_count/[2,3] is called or auto_commit is turned off. Attempts to use the connection from another process will fail. This will not affect the connection. On the other hand, if the client process dies the connection will be terminated.

Timeouts

All requests made by the client to the connection are synchronous. If the timeout is used and expires the client process will exit with reason timeout. Probably the right thing to do is let the client die and perhaps be restarted by its supervisor. But if the client chooses to catch this timeout, it is a good idea to wait a little while before trying again. If there are too many consecutive timeouts that are caught the connection process will conclude that there is something radically wrong and terminate the connection.

Guards

All API-functions are guarded and if you pass an argument of the wrong type a runtime error will occur. All input parameters to internal functions are trusted to be correct. It is a good programming practise to only distrust input from truly external sources. You are not supposed to catch these errors, it will only make the code very messy and much more complex, which introduces more bugs and in the worst case also covers up the actual faults. Put your effort on testing instead, you should trust your own input.

1.4.2 The whole picture

As the Erlang ODBC application relies on third party products and communicates with a database that probably runs on an other computer in the network there are plenty of things that might go wrong. To fully understand the things that might happen it facilitate to know the design of the Erlang ODBC application, hence here follows a short description of the current design.

Note:

Please note that design is something, that not necessarily will, but might change in future releases. While the semantics of the API will not change as it is independent of the implementation.
When you do `application:start(odbc)` the only thing that happens is that a supervisor process is started. For each call to the API function `connect/2` a process is spawned and added as a child to the Erlang ODBC supervisor. The supervisors only tasks are to provide error-log reports, if a child process should die abnormally, and the possibility to do a code change. Only the client process has the knowledge to decide if this connection managing process should be restarted.

The Erlang connection process spawned by `connect/2`, will open a port to a c-process that handles the communication with the database through Microsoft's ODBC API. The Erlang port will be kept open for exit signal propagation, if something goes wrong in the c-process and it exits we want know as mush as possible about the reason. The main communication with the c-process is done through sockets. The C-process consists of two threads, the supervisor thread and the database handler thread. The supervisor thread checks for shutdown messages on the supervisor socket and the database handler thread receives requests and sends answers on the database socket. If the database thread seems to hang on some database call, the Erlang control process will send a shutdown message on the supervisor socket, in this case the c-process will exit. If the c-process crashes/exports it will bring the Erlang-process down too and vice versa i.e. the connection is terminated.
Chapter 1: Erlang ODBC User's Guide

**Note:**
The function `connect/2` will start the odbc application if that is not already done. In this case a supervisor information log will be produced stating that the odbc application was started as a temporary application. It is really the responsibility of the application that uses the API too make sure it is started in the desired way.

**Error types**
The types of errors that may occur can be divide into the following categories.

- **Configuration problems** - Everything from that the database was not set up right to that the c-program that should be run through the erlang port was not compiled for your platform.

- **Errors discovered by the ODBC driver** - If calls to the ODBC-driver fails due to circumstances that can not be controlled by the Erlang ODBC application programmer, an error string will be dug up from the driver. This string will be the `Reason` in the `{error, Reason}` return value. How good this error message is will of course be driver dependent. Examples of such circumstances are trying to insert the same key twice, invalid SQL-queries and that the database has gone off line.

- **Connection termination** - If a connection is terminated in an abnormal way, or if you try to use a connection that you have already terminated in a normal way by calling `disconnect/1`, the return value will be `{error, connection_closed}`. A connection could end abnormally because of an programming error in the Erlang ODBC application, but also if the ODBC driver crashes.

- **Contextual errors** - If API functions are used in the wrong context, the `Reason` in the error tuple will be a descriptive atom. For instance if you try to call the function `last/[1,2]` without first calling `select_count/[2,3]` to associate a result set with the connection. If the ODBC-driver does not support some functions, or if you disabled some functionality for a connection and then try to use it.
Erlang ODBC Reference Manual

Short Summaries

- Erlang Module **odbc** [page 15] - Erlang ODBC application

**odbc**

The following functions are exported:

- `commit(ConnectionReference, CommitMode) ->` [page 16] Commits or rollbacks a transaction.
- `commit(ConnectionReference, CommitMode, TimeOut) -> ok | {error, Reason}` [page 16] Commits or rollbacks a transaction.
- `connect(ConnectStr, Options) -> {ok, ConnectionReference} | {error, Reason}` [page 16] Opens a connection to the database.
- `disconnect(ConnectionReference) -> ok | {error, Reason}` [page 18] Closes a connection to a database.
- `describe_table(ConnectionReference, Table) ->` [page 18] Queries the database to find out the data types of the columns of the table Table.
- `describe_table(ConnectionReference, Table, Timeout) -> {ok, Description} | {error, Reason}` [page 18] Queries the database to find out the data types of the columns of the table Table.
- `first(ConnectionReference) ->` [page 18] Returns the first row of the result set and positions a cursor at this row.
- `first(ConnectionReference, Timeout) -> {selected, ColNames, Rows} | {error, Reason}` [page 18] Returns the first row of the result set and positions a cursor at this row.
- `last(ConnectionReference) ->` [page 18] Returns the last row of the result set and positions a cursor at this row.
- `last(ConnectionReference, TimeOut) -> {selected, ColNames, Rows} | {error, Reason}` [page 18] Returns the last row of the result set and positions a cursor at this row.
- `next(ConnectionReference) ->` [page 18] Returns the next row of the result set relative the current cursor position and positions the cursor at this row.
- \texttt{next(ConnectionReference, TimeOut) \to \{\text{selected}, \text{ColNames}, \text{Rows}\} | \{\text{error}, \text{Reason}\}}
  
  \textit{[page 18]} Returns the next row of the result set relative the current cursor position and positions the cursor at this row.

- \texttt{param_query(ConnectionReference, SQLQuery, Params) \to \text{Execute a parameterized SQL query.}}
  
- \texttt{param_query(ConnectionReference, SQLQuery, Params, TimeOut) \to \text{Execute a parameterized SQL query.}}
  
- \texttt{prev(ConnectionReference) \to \text{Returns the previous row of the result set relative the current cursor position and positions the cursor at this row.}}

- \texttt{prev(ConnectionReference, TimeOut) \to \{\text{selected}, \text{ColNames}, \text{Rows}\} | \{\text{error}, \text{Reason}\}}
  
  \textit{[page 19]} Returns the previous row of the result set relative the current cursor position and positions the cursor at this row.

- \texttt{sql_query(ConnectionReference, SQLQuery) \to \text{Executes a SQL query or a batch of SQL queries. If it is a SELECT query the result set is returned, on the format \{\text{selected}, \text{ColNames}, \text{Rows}\}. For other query types the tuple \{\text{updated}, \text{NRows}\} is returned, and for batched queries, if the driver supports them, this function can also return a list of result tuples.}}

- \texttt{sql_query(ConnectionReference, SQLQuery, TimeOut) \to \text{Execute a SQL query or a batch of SQL queries. If it is a SELECT query the result set is returned, on the format \{\text{selected}, \text{ColNames}, \text{Rows}\}. For other query types the tuple \{\text{updated}, \text{NRows}\} is returned, and for batched queries, if the driver supports them, this function can also return a list of result tuples.}}

- \texttt{select_count(ConnectionReference, SelectQuery) \to \text{Executes a SQL SELECT query and associates the result set with the connection. A cursor is positioned before the first row in the result set and the tuple \{\text{ok}, \text{NrRows}\} is returned.}}

- \texttt{select_count(ConnectionReference, SelectQuery, TimeOut) \to \{\text{ok}, \text{NrRows}\} | \{\text{error}, \text{Reason}\}}
  
  \textit{[page 20]} Executes a SQL SELECT query and associates the result set with the connection. A cursor is positioned before the first row in the result set and the tuple \{\text{ok}, \text{NrRows}\} is returned.

- \texttt{select(ConnectionReference, Position, N) \to \text{Selects } N \text{ consecutive rows of the result set.}}

- \texttt{select(ConnectionReference, Position, N, TimeOut) \to \{\text{selected}, \text{ColNames}, \text{Rows}\} | \{\text{error}, \text{Reason}\}}
  
  \textit{[page 20]} Selects } N \text{ consecutive rows of the result set.
This application provides an Erlang interface to communicate with relational SQL-databases. It is built on top of Microsofts ODBC interface and therefore requires that you have an ODBC driver to the database that you want to connect to.

**Note:**
The functions `first/[1,2]`, `last/[1,2]`, `next/[1,2]`, `prev[1,2]` and `select/[3,4]` assumes there is a result set associated with the connection to work on. Calling the function `select_count/[2,3]` associates such a result set with the connection. Calling `select_count` again will remove the current result set association and create a new one. Calling a function which does not operate on an associated result sets, such as `sql_query/[2,3]`, will remove the current result set association. Alas some drivers only support sequential traversal of the result set, e.i. they do not support what in the ODBC world is known as scrollable cursors. This will have the effect that functions such as `first/[1,2]`, `last/[1,2]`, `prev[1,2]`, etc will return `error, driver_does_not_support_function`.

**COMMON DATA TYPES**
Here follows type definitions that are used by more than one function in the ODBC API.

**Note:**
The type `TimeOut` has the default value `infinity`, so for instance: `commit(ConnectionReference, CommitMode)` is the same as `commit(ConnectionReference, CommitMode, infinity)`. If the timeout expires the client will exit with the reason `timeout`.

- ConnectionReference - as returned by `connect/2`
- `TimeOut = Milliseconds | infinity`
- `Milliseconds = integer()`
- `CommonReason = connection_closed | term()` - some kind of explanation of what went wrong
- `String = list of ASCII characters`
- `ColName = String()` - Name of column in the result set
ColNames - [ColName] - e.g. a list of the names of the
selected columns in the result set.

Row = {Value} - Tuple of column values e.g. one row of the
result set.

Value = null | term() - A column value.

Rows = [Row] - A list of rows from the result set.

ResultTuple = {updated, NRows} | {selected, ColNames, Rows}

NRows = integer() - The number of affected rows for UPDATE,
INSERT, or DELETE queries. For other query types the value
is driver defined, and hence should be ignored.

ODBCDataType = sql_integer | sql_smallint | sql_tinyint |
{sql_decimal, Precison, Scale} | {sql_numeric, Precison, Scale} |
{sql_char, Size} | {sql_varchar, Size} | {sql_float, Precision} |
{sql_float, Precision} | sql_real | sql_double | sql_bit | atom()

Precision = integer()
Scale = integer()
Size = integer()

ERROR HANDLING

The error handling strategy and possible errors sources are described in the Erlang
ODBC User's Guide. [page 9]

Exports

commit(ConnectionReference, CommitMode) ->
commit(ConnectionReference, CommitMode, TimeOut) -> ok | {error, Reason}

Types:
• CommitMode = commit | rollback
• Reason = not_an_explicit_commit_connection |
  process_not_owner_of_odbc_connection | CommonReason
• See also common data types.
Commits or rollbacks a transaction. Needed on connections where automatic commit is
turned off.

connect(ConnectStr, Options) -> {ok, ConnectionReference} | {error, Reason}

Types:
• ConnectionReference - should be used to acess the connection.
ConnectStr

An example of a connection string: "DSN=sql-server;UID=alladin;PWD=sesame" where DSN is your ODBC Data Source Name, UID is a database user id and PWD is the password for that user. These are usually the attributes required in the connection string, but some drivers have other driver specific attributes, for example "DSN=Oracle8;DBQ=gandalf;UID=alladin;PWD=sesame" where DBQ is your TNSNAMES.ORA entry name e.g. some Oracle specific configuration attribute.

Options = [] | [Option]

All options has default values.

Option = {auto_commit, AutoCommitMode} | {timeout, Milliseconds} | {tuple_row, TupleMode} | {scrollable Cursors, UseSrollableCursors} | {trace_driver, TraceMode}

The default timeout is infinity

AutoCommitMode = on | off

Default is on.

TupleMode = on | off

Default is on. The option is deprecated and should not be used in new code.

UseSrollableCursors = on | off

Default is on.

TraceMode = on | off

Default is off.

Reason = port_program_executable_not_found | CommonReason

See also common data types.

Opens a connection to the database. The connection is associated with the process that created it and can only be accessed through it. This function may spawn new processes to handle the connection. These processes will terminate if the process that created the connection dies or if you call disconnect/1.

If automatic commit mode is turned on, each query will be considered as an individual transaction and will be automatically committed after it has been executed. If you want more than one query to be part of the same transaction the automatic commit mode should be turned off. Then you will have to call commit/3 explicitly to end a transaction.

As default result sets are returned as a lists of tuples. The TupleMode option still exists to keep some degree of backwards compatibility. If the option is set to off, result sets will be returned as a lists of lists instead of a lists of tuples.

Scrollable cursors are nice but causes some overhead. For some connections speed might be more important than flexible data access and then you can disable scrollable cursor for a connection, limiting the API but gaining speed.

If trace mode is turned on this tells the ODBC driver to write a trace log to the file SQL.LOG that is placed in the current directory of the erlang emulator. This information may be useful if you suspect there might be a bug in the erlang ODBC application, and it might be relevant for you to send this file to our support. Otherwise you will probably not have much use of this.

Note:

For more information about the ConnectStr see description of the function SQLDriverConnect in [1].
disconnect(ConnectionReference) -> ok | {error, Reason}

Types:
- Reason = process_not_owner_of_odbc_connection
- See also common data types.

Closes a connection to a database. This will also terminate all processes that may have been spawned when the connection was opened. This call will always succeed. If the connection can not be disconnected gracefully it will be brutally killed. However you may receive an error message as result if you try to disconnect a connection started by another process.

describe_table(ConnectionReference, Table) ->

describe_table(ConnectionReference, Table, Timeout) -> {ok, Description} | {error, Reason}

Types:
- Table = string() - Name of database table.
- Description = [{Coloname, ODBCDataType}]
- See also common data types.

Queries the database to find out the ODBC data types of the columns of the table Table.

first(ConnectionReference) ->

first(ConnectionReference, Timeout) -> {selected, ColNames, Rows} | {error, Reason}

Types:
- Reason = result_set_does_not_exist | driver_does_not_support_function | scrollable.Cursors_disabled | process_not_owner_of_odbc_connection | CommonReason
- See also common data types.

Returns the first row of the result set and positions a cursor at this row.

last(ConnectionReference) ->

last(ConnectionReference, TimeOut) -> {selected, ColNames, Rows} | {error, Reason}

Types:
- Reason = result_set_does_not_exist | driver_does_not_support_function | scrollable.Cursors_disabled | process_not_owner_of_odbc_connection | CommonReason
- See also common data types.

Returns the last row of the result set and positions a cursor at this row.

next(ConnectionReference) ->

next(ConnectionReference, TimeOut) -> {selected, ColNames, Rows} | {error, Reason}

Types:
- Reason = result_set_does_not_exist | process_not_owner_of_odbc_connection | CommonReason
- See also common data types.
Returns the next row of the result set relative the current cursor position and positions
the cursor at this row. If the cursor is positioned at the last row of the result set when
this function is called the returned value will be \{selected, ColNames, []\} e.i. the list
of row values is empty indicating that there is no more data to fetch.

\[\text{param_query}(:\text{ConnectionReference, SQLQuery, Params} \rightarrow \text{ResultTuple} | \{\text{error, Reason}\})\]

Types:
- \text{SQLQuery} = \text{String()} - a SQL query with parameter markers/place holders in form
  of question marks.
- \text{Params} = \{\text{ODBCDataType, [Values]}\}
- \text{Values} = \text{term()} - Must be consistent with the Erlang data type that corresponds to
  the ODBC data type \text{ODBCDataType}
- See also common data types.

Executes a parameterized SQL query. For an example see the “Using the Erlang API” [page 4]

**Note:**
Use the function \text{describe_table}/[2,3] to find out which ODBC data type that is
expected for each column of that table. If a column has a data type that is described
with capital letters, alas it is not currently supported by the param_query function.
To know which Erlang data type corresponds to an ODBC data type see the Erlang

\[\text{prev}(:\text{ConnectionReference} \rightarrow \{\text{selected, ColNames, Rows}\} | \{\text{error, Reason}\})\]

Types:
- \text{Reason} = \text{result_set_does_not_exist | driver_does_not_support_function | scrollable_cursors_disabled | process_not_owner_of_odbc_connection | CommonReason}
- See also common data types.

Returns the previous row of the result set relative the current cursor position and
positions the cursor at this row.

\[\text{sql_query}(:\text{ConnectionReference, SQLQuery} \rightarrow \text{ResultTuple} | \{\text{error, Reason}\})\]

Types:
- \text{SQLQuery} = \text{String} - The string may be composed by several SQL-queries separated
  by a ; this is called a batch.
- \text{Reason} = \text{process_not_owner_of_odbc_connection | CommonReason}
- See also common data types.
Executes a SQL query or a batch of SQL queries. If it is a SELECT query the result set is
returned, on the format \{selected, ColNames, Rows\}. For other query types the
tuple \{updated, NRows\} is returned, and for batched queries, if the driver supports
them, this function can also return a list of result tuples.

**Note:**
Some drivers may not have the information of the number of affected rows available
and then the return value may be \{updated, undefined\}.
The list of column names is ordered in the same way as the list of values of a row, e.g.
the first ColName is associated with the first Value in a Row.

```erlang
select_count(ConnectionReference, SelectQuery) ->
sselect_count(ConnectionReference, SelectQuery, TimeOut) -> {ok, NRows} | {error, Reason}
```

Types:
- **SelectQuery = String**
  SQL SELECT query.
- **NRows = integer() | undefined**
  Number of row in the result set.
- **Reason = process_not_owner_of_odbc_connection | CommonReason**
  See also common data types.

Executes a SQL SELECT query and associates the result set with the connection. A
cursor is positioned before the first row in the result set and the tuple \{ok, NRows\} is
returned.

**Note:**
Some drivers may not have the information of the number of rows in the result set, then NRows will have the value undefined.

```erlang
select(ConnectionReference, Position, N) ->
sselect(ConnectionReference, Position, N, TimeOut) -> {selected, ColNames, Rows} | {error, Reason}
```

Types:
- **Position = next | {relative, Pos} | {absolute, Pos}**
  Selection strategy, determines at which row in the result set to start the selection.
- **Pos = integer()**
  Should indicate a row number in the result set. When used together with the option
  relative it will be used as an offset from the current cursor position, when used
  together with the option absolute it will be interpreted as a row number.
- **Reason = result_set_does_not_exist | driver_does_not_support_function | scrollable_cursors_disabled | process_not_owner_of_odbc_connection | CommonReason**
See also common data types.

Selects \( N \) consecutive rows of the result set. If \( \text{Position is next} \) it is semantically equivalent of calling \( \text{next/}[1,2]^N \) times. If \( \text{Position is relative, Pos} \), \( \text{Pos} \) will be used as an offset from the current cursor position to determine the first selected row. If \( \text{Position is absolute, Pos} \), \( \text{Pos} \) will be the number of the first row selected. After this function has returned the cursor is positioned at the last selected row. If there is less then \( N \) rows left of the result set the length of \( \text{Rows} \) will be less than \( N \). If the first row to select happens to be beyond the last row of the result set, the returned value will be \( \{ \text{selected, CoLNames,[]} \} \) i.e. the list of row values is empty indicating that there is no more data to fetch.
