Chapter 1

The Orber Application

1.1 Content Overview

The Orber documentation is divided into three sections:

- PART ONE - The User’s Guide
  Description of the Orber Application including IDL-to-Erlang language mapping, services and a small tutorial demonstrating the development of a simple service.

- PART TWO - Release Notes
  A concise history of Orber.

- PART THREE - The Reference Manual
  A quick reference guide, including a brief description, to all the functions available in Orber.

1.2 Brief Description of the User’s Guide

The User’s Guide contains the following parts:

- ORB kernel and IIOP support
- Interface Repository
- IDL to Erlang mapping
- CosNaming Service
- Resolving initial reference from Java or C++
- Tutorial - creating a simple service
- CORBA Exceptions
- Interceptors
- OrberWeb
- Debugging
Chapter 1: The Orber Application

1.2.1 ORB Kernel and IIOP Support

The ORB kernel which has IIOP support will allow the creation of persistent server objects in Erlang. These objects can also be accessed via Erlang and Java environments. For the moment a Java enabled ORB is needed to generate Java from IDL to use Java server objects (this has been tested using OrbixWeb).

1.2.2 Interface Repository

The IFR is an interface repository used for some type-checking when coding/decoding IIOP. The IFR is capable of storing all interfaces and declarations of OMG IDL.

1.2.3 IDL to Erlang Mapping

The OMG IDL mapping for Erlang, which is necessary to access the functionality of Orber, is described. The mapping structure is included as the basic and the constructed OMG IDL types references, invocations and Erlang characteristics. An example is also provided.

1.2.4 CosNaming Service

Orber contains a CosNaming compliant service.

1.2.5 Resolving Initial References from Java or C++

A couple of classes are added to Orber to simplify initial reference access from Java or C++. Resolving initial reference from Java

A class with only one method which returns an IOR on the external string format to the INIT object (see “Interoperable Naming Service” specification).

Resolving initial reference from C++

A class (and header file) with only one method which returns an IOR on the external string format to the INIT object (see “Interoperable Naming Service” specification).

1.2.6 Orber Stub/Skeleton

An example which describes the API and behavior of Orber stubs and skeletons.

1.2.7 CORBA Exceptions

A listing of all system exceptions supported by Orber and how one should handle them. This chapter also describe how to generate user defined exceptions.

1.2.8 Interceptors

Describes how to implement and activate interceptors.

1.2.9 OrberWeb

Offers the possibility to administrate and supervise Orber via a GUI.
1.2.10 Debugging

Describes how to use different tools when debugging and/or developing new applications using Orber. Also includes a FAQ, which deal with the most common mistakes when using Orber.
Chapter 2

Introduction to Orber and the IFR

This chapter contains an introduction to Orber and the IFR (Interface Repository).

2.1 Introduction to Orber

2.1.1 Overview

The Orber application is a CORBA compliant Object Request Brokers (ORB), which provides CORBA functionality in an Erlang environment. Essentially, the ORB channels communication or transactions between nodes in a heterogeneous environment.

CORBA (Common Object Request Broker Architecture) provides an interface definition language allowing efficient system integration and also supplies standard specifications for some services.

The Orber application contains the following parts:

- ORB kernel and IIOP support
- Interface Repository
- Interface Definition Language Mapping for Erlang
- CosNaming Service

Benefits

Orber provides CORBA functionality in an Erlang environment that enables:

- Platform interoperability and transparency
  Orber enables communication between OTP applications or Erlang environment applications and other platforms; for example, Windows NT, Solaris etc, allowing platform transparency. This is especially helpful in situations where there are many users with different platforms. For example, booking airline tickets would require the airline database and hundreds of travel agents (who may not have the same platform) to book seats on flights.
Chapter 2: Introduction to Orber and the IFR

- Application level interoperability and transparency

As Orber is a CORBA compliant application, its purpose is to provide interoperability and transparency on the application level. Orber simplifies the distributed system software by defining the environment as objects, which in effect, views everything as identical regardless of programming languages. Previously, time-consuming programming was required to facilitate communication between different languages. However, with CORBA compliant Orber the Application Programmer is relieved of this task. This makes communication on an application level relatively transparent to the user.

Purpose and Dependencies

The system architecture and OTP dependencies of Orber are illustrated in figure 1 below:

![Figure 1: Orber Dependencies and Structure.](image)

Orber is dependent on Mnesia (see the Mnesia documentation) - an Erlang database management application used to store object information.

**Note:**
Although Orber does not have a run-time application dependency to IC (an IDL compiler for Erlang), it is necessary when building services and applications. See the IC documentation for further details.
This simplified illustration in figure 2 demonstrates how Orber can facilitate communication in a heterogeneous environment. The Erlang Nodes running OTP and the other Node running applications written in Java can communicate via an ORB (Object Request Broker). Using Orber means that CORBA functions can be used to achieve this communication.

For example, if one of the above nodes requests an object, it does not need to know if that object is located on the same, or different, Erlang or Java nodes. The ORB will channel the information creating platform and application transparency for the user.

Prerequisites

To fully understand the concepts presented in the documentation, it is recommended that the user is familiar with distributed programming and CORBA (Common Object Request Broker Architecture). Recommended reading includes Open Telecom Platform Documentation Set and Concurrent Programming in Erlang.

2.2 The Orber Application

2.2.1 ORB Kernel and IIOP

This chapter gives a brief overview of the ORB and its relation to objects in a distributed environment and the usage of Domains in Orber. Also Internet-Inter ORB Protocol (IIOP) is discussed and how this protocol facilitates communication between ORBs to allow the access of persistent server objects in Erlang.
2.2.2 The Object Request Broker (ORB)

An ORB kernel can be best described as the middle-ware, which creates relationships between clients and servers, but is defined by its interfaces. This allows transparency for the user, as they do not have to be aware of where the requested object is located. Thus, the programmer can work with any other platform provided that an IDL mapping and interfaces exist.

The IDL mapping which is described in a later chapter is the translator between other platforms, and languages. However, it is the ORB, which provides objects with a structure by which they can communicate with other objects.

ORBs intercept and direct messages from one object, pass this message using IIOP to another ORB, which then directs the message to the indicated object.

An ORB is the base on which interfaces, communication stubs and mapping can be built to enable communication between objects. Orber uses domains to group objects of different nodes.

How the ORB provides communication is shown very simply in figure 1 below:

![Diagram of ORB communication](image)

**Figure 2.3: Figure 1: How the Object Request Broker works.**

The domain in Orber gives an extra aspect to the distributed object environment as each domain has one ORB, but it is distributed over a number of object in different nodes. The domain binds objects on
nodes more closely than distributed objects in different domains. The advantage of a domain is that a faster communication exists between nodes and objects of the same domain. An internal communication protocol (other than IIOP) allows a more efficient communication between these objects.

**Note:**
Unlike objects, domains can only have one name so that no communication ambiguities exist between domains.

### 2.2.3 Internet Inter-Object Protocol (IIOP)

IIOP is a communication protocol developed by the OMG to facilitate communication in a distributed object-oriented environment.

Figure 2 below demonstrates how IIOP works between objects:

![IIOP communication between domains and objects](image)

Figure 2.4: Figure 2: IIOP communication between domains and objects.

**Note:**
Within the Orber domains the objects communicate without using the IIOP. However, the user is unaware of the difference in protocols, as this difference is not visible.
2.3 Interface Repository

2.3.1 Interface Repository (IFR)

The IFR is an interface repository built on the Mnesia application. Orber uses the IFR for some type-checking when coding/decoding IIOP. The IFR is capable of storing all interfaces and declarations of OMG IDL.

The interface repository is mainly used for dynamical interfaces, and as none are currently supported this function is only really used for retrieving information about interfaces.

Functions relating to the manipulation of the IFR including, initialization of the IFR, as well as, locating, creating and destroying initial references are detailed further in the Manual Pages.
Chapter 3

Installing Orber

3.1 Installation Process

This chapter describes how to install Orber in an Erlang Environment.

3.1.1 Preparation

To begin with, you must decide if you want to run Orber as a:

- **Single node (non-distributed)** - all communication with other Orber instances and ORB's supplied by other vendors use the OMG GIOP protocol.
- **Multi node (distributed)** - all Orber nodes, within the same domain, communicate via the Erlang distribution protocol. For all other Orber instances, i.e. not part of the same domain, and ORB's supplied by other vendors, the OMG GIOP protocol is used.

Which approach to use is highly implementation specific, but a few things you should consider:

- All nodes within an Orber domain should have the same security level.
- If the capacity is greater than load (volume of traffic) a single-node Orber might be a good solution.
- In some cases the distributed system architecture requires a single-node Orber installation.
- A multi-node Orber makes it possible to load balance and create a more fault tolerant system. The Objects can also have a uniform view if you use distributed Mnesia tables.
- Since the GIOP protocol creates a larger overhead than the Erlang distribution protocol, the performance will be better when communicating with Objects within the same Orber domain compared with inter ORB communication (GIOP).

You also have to decide if you want Orber to store internal data using disc copies and/or ram copies. Which storage type you should depends if/how you intend to use Mnesia in your application. If you intend to use disc copies you must start with creating a Mnesia schema, which contain information about the location of the Erlang nodes where Orber is planned to be run. For more background information, see the Mnesia documentation.

In some cases it is absolutely necessary to change the default configuration of Orber. For example, if two Orber-ORB's shall be able to communicate via GIOP, they must have a unique domain. Consult the configuration settings [page 14] section. If you encounter any problems; see the chapter about Debugging in this User's Guide.
3.1.2 Jump Start Orber

The easiest way to start Orber is to use `orber:jump_start(Port)`, which starts a single-node ORB with (most likely) a unique domain (i.e. “IP-number:Port”). This function may only be used during development and testing. For any other situation, install and start Orber as described in the following sections. The listen port, i.e. `iiop_port` configuration parameter, is set to the supplied Port.

**Warning:**
How Orber is configured when using `orber:jump_start(Port)` may change at any time without warning. Hence, this operation must not be used in systems delivered to a customer.

3.1.3 Install Single Node Orber

Since a single node Orber communicates via the OMG GIOP protocol it is not necessary to start the Erlang distribution (i.e. using `-name/-sname`).

If we use `ram_copies` there is no need for creating a disc based schema. Simply use:

```
erl> mnesia:start().
erl> corba:orb_init([{domain, "MyRAMSingleNodeORB"}]).
erl> orber:install([node()]), [{ifr_storage_type, ram_copies}]).
erl> orber:start().
```

If your installation requires `disc_copies` you must begin with creating a Mnesia schema. Otherwise, the installation is similar to a RAM installation:

```
erl> mnesia:create_schema([node()]).
erl> mnesia:start().
erl> corba:orb_init([{domain, "MyDiscSingleNodeORB"}]).
erl> orber:install([node()]), [{ifr_storage_type, disc_copies},
                                   {nameservice_storage_type, disc_copies}]).
erl> orber:start().
```

You can still choose to store the IFR data as `ram_copies`, but then the data must be re-installed (i.e. invoke `orber:install/2`) if the node is restarted. Hence, since the IFR data is rather static you should use `disc_copies`. For more information see the `orber` section in the reference manual.

If you do not need to change Orber's configuration you can skip `orb_init/1` [page 134]. But, you should at least set the IIOP timeout parameters.

**Note:**
When starting Orber as lightweight, `mnesia` and `orber:install/*` are not required. You must, however, use the configuration [page 14] parameter `lightweight`. 
3.1.4 Install RAM Based Multi Node Orber

Within a domain Orber uses the Erlang distribution protocol. Hence, you must start it first by, for example, using:

hostA> erl -sname nodeA

In this example, we assume that we want to use two nodes; nodeA and nodeB. Since Mnesia must know which other nodes should be a part of the distribution we either need to add the Mnesia configuration parameter extra_db_nodes or use mnesia:change_config/2. To begin with, Mnesia must be started on all nodes before we can install Orber:

nodeA@hostA> mnesia:start().
nodeA@hostA> mnesia:change_config(extra_db_nodes, [nodeA@hostA, nodeB@hostB]).

After that the above have been repeated on nodeB we must first make sure that both nodes will use the same domain name, then we can install Orber:

nodeA@hostA> corba:orb_init([{domain, "MyRAMMultiNodeORB"}]).
nodeA@hostA> orber:install([nodeA@hostA, nodeB@hostB], [{ifr_storage_type, ram_copies}]).
nodeA@hostA> orber:start().

Note that you can only invoke orber:install/1/2 on one of the nodes. Now we can start Orber on the other node:

nodeB@hostB> corba:orb_init([{domain, "MyRAMMultiNodeORB"}]).
nodeB@hostB> orber:start().

3.1.5 Install Disc Based Multi Node Orber

As for RAM based multi-node Orber installations, the Erlang distribution must be started (e.g. erl -sname nodeA). The major difference is that when it is disc based a Mnesia schema must be created:

nodeA@hostA> mnesia:create_schema([nodeA@hostA, nodeB@hostB]).
nodeA@hostA> mnesia:start().

In this example, we assume that we want to use two nodes; nodeA and nodeB. Since it is not possible to create a schema on more than one node. Hence, all we have to do is to start Mnesia (i.e. invoke mnesia:start()) on nodeB.

After Mnesia have been started on all nodes, you must confirm that all nodes have the same domain name, then Orber is ready to be installed:

nodeA@hostA> corba:orb_init([{domain, "MyDiscMultiNodeORB"}]).
nodeA@hostA> orber:install([nodeA@hostA, nodeB@hostB], [{ifr_storage_type, disc_copies}]).
nodeA@hostA> orber:start().

Note that you can only invoke orber:install/1/2 on one of the nodes. Now we can start Orber on the other node:

nodeB@hostB> corba:orb_init([{domain, "MyDiscMultiNodeORB"}]).
nodeB@hostB> orber:start().
3.1.6 Running Java clients against Orber.

If you intend to run Java clients and your Java ORB does not support the Interoperable Naming Service (INS), a specific

</OTP_INSTALLPATH>/lib/orber-<current-version>/priv

must be added to your CLASSPATH variable to allow Orber support for the initial references. For more information about INS, see the Name Service chapter in this User’s Guide.

3.2 Configuration

It is essential that one configure Orber properly, to avoid, for example, malicious attacks and automatically terminate IIOP connections no longer in use. An easy way to extract information about Orber’s configuration parameters is to invoke the operation orber:info/1/2 [page 155]. Orber offer the following configuration parameters:

<table>
<thead>
<tr>
<th>Key</th>
<th>Range</th>
<th>Default</th>
</tr>
</thead>
<tbody>
<tr>

Table 3.1: Orber Configuration Parameters

Comments on the table 'Orber Configuration Parameters':

**domain** Since Orber domains, they are supposed to communicate via IIOP, MUST have unique names, communication will fail if two domains have the same name. The domain name MAY NOT contain ~ (i.e. \007).

**iiop port** If set to 0 the OS will pick any vacant port.

Note: On a UNIX system it is preferable to have a IIOP port higher than 1023, since it is not recommended to run Erlang as a root user.

**nat iiop port** See also Firewall Configuration [page 20].

**iiop out ports** When set to 0 any available port will be used. If a range is specified, Orber will only use the local ports within the interval when trying to connect to another ORB (Orber acts as a client ORB). If all ports are in use communication will fail. Hence, it is absolutely necessary to set
Chapter 3: Installing Orber

**iiop_connection_timeout** as well. Otherwise, connections no longer in use will block further communication. If one use, for example, `erl -orber iiop_out_ports "{5000,5020}"`, Orber will only use port 5000 to 5020 when connecting. If communicating via SSL, make sure you use a version that supports the local `{port, Port}` option. See also Firewall Configuration [page 20].

**iiop_max_fragments** Limits the number of IIOP fragments allowed per request.

**iiop_max_in_requests** Limits the number of concurrent incoming requests per incoming connection.

**iiop_max_in_connections** Limits the number of concurrent incoming connections.

**iiop_backlog** Defines the maximum length the queue of pending incoming connections may grow to.

**iiop_packet_size** Defines the maximum size of incoming requests. If this limit is exceeded, the connection is closed.

**ip_address** This option is used if Orber only should listen on a specific IP interface on a multi-interface host or if exported IOR:s should contain multiple components. The value is the IPv4 or IPv6 address as a string.

**ip_address_local** This option defines the default local interface Orber will use when connecting to another ORB via IIOP, i.e., Orber act as the client side ORB. The value is a IPv4 or IPv6 address as a string. It is possible to override `ip_address_local` by defining `iiop_acl` or passing the Orber generic interface Context. If this option is not used, the underlying will choose which interface to use. For more information, see the Interface Configuration [page 22] section.

**nat_ip_address** The value is the IP address as a string (IPv4 or IPv6) or `{multiple, IPList}`. See also Firewall Configuration [page 20].

**objectkeys_gc_time** This option should be set if objects are started using the option `{persistent, true}`. The value is integer() seconds.

**giop_version** Defines the default GIOP protocol version.

**iiop_setup_connection_timeout** The value is an integer (seconds) or the atom infinity. This option is only valid for client-side connections. If this option is set, attempts to connect to other ORB:s will timeout after the given time limit. Note, if the time limit is large the TCP protocol may timeout before the supplied value.

**iiop_connection_timeout** The value is an integer (timeout in seconds between 0 and 1000000) or the atom infinity. This option is only valid for client object connections, i.e., will have no effect on server connections. Setting this option will cause client connections to be terminated, if and only if, there are no pending requests. If there are a client still waiting for a reply, Orber will try again after the given seconds have passed. The main purpose for this option is to reduce the number of open connections; it is, for example, not necessary to keep a connection, only used once a day, open at all time.

**iiop_in_connection_timeout** The same as for `iiop_connection_timeout`. The only difference is that this option only affects incoming connections (i.e. Orber act as server-side ORB.

**iiop_timeout** The value is an integer (timeout in seconds between 0 and 1000000) or the atom infinity. This option is only valid on the client side. Setting this option, cause all intra-ORB requests to timeout and raise a system exception, e.g. `TIMEOUT`, if no replies are delivered within the given time limit.

**interceptors** If one set this parameter, e.g., `erl -orber interceptors "[native, ['myInterceptor']]", Orber will use the supplied interceptor(s) for all inter-ORB communication. `myInterceptor` is the module name of the interceptor. For more information, see the interceptor chapter in the User's Guide and the Reference Manual.

**local_interceptors** If defined, its value will be used when activating local interceptors via Orber Environment Flags [page 18]. If not defined, but the flag is set, Orber will use the value of the interceptors parameter.
### 3.2: Configuration

**lightweight**
This option must be set if Orber is supposed to be started as lightweight. The value is a list of RemoteModifiers, equal to the `orber:resolve_initial_references remote/2` argument. The list must contain Orber nodes addresses, to which we have access and are not started as lightweight.

**orbInitRef**
Setting this option, e.g., `erl -orber orbInitRef \"NameService=corbaloc::host.com/NameService\"`, will alter the location from where `corba:resolve_initial_references(Key)` tries to find an object matching the given Key. The keys will also appear when invoking `corba:list_initial_services()`. This variable overrides `orbDefaultInitRef`.

**orbDefaultInitRef**
If a matching Key for `orbInitRef` is not found, and this variable is set, it determines the location from where `orber:resolve_initial_references(Key)` tries to find an object matching the given Key. Usage: `erl -orber orbDefaultInitRef \"corbaloc::host.com\"`.

**orber_debug_level**
The range is 0 to 10. Using level 10 is the most verbose configuration. This option will generate reports, using the `error_logger`, for abnormal situations. It is not recommended to use this option for delivered systems since some of the reports is not to be considered as errors. The main purpose is to assist during development.

**flags**
No flags are activated in the default case. The available configuration settings are described in Orber Environment Flags [page 18].

**iiop_acl**
This option must be activated by setting Orber Environment Flags [page 18] parameter. The value of this parameter shall be a list of [[Direction, Filter]] and/or [[Direction, Filter, Interfaces]]. The Direction, tcp_in, ssl_in, tcp_out or ssl_out, determines if the Access Control List (ACL) applies to incoming or outgoing connections and IIOP or IIOP over SSL. The Filter uses an extended format of Classless Inter Domain Routing (CIDR). For example, "123.123.123.10" limits the connection to that particular host, while "123.123.123.10/17" allows connections to or from any host equal to the 17 most significant bits. Orber also allow the user to specify a certain port or port range, for example, "123.123.123.10/17#4001" and "123.123.123.10/17#4001/5001" respectively. IPv4 or none compressed IPv6 strings are accepted.

The list of Interfaces, IPv4 or IPv6 strings, may only contain one address for outgoing connections. For incoming connections, the Interfaces list may contain several IP strings. If set for outgoing connections, and access is granted, Orber will use that local interface when connecting to the server-side ORB. For incoming connections, the client-side ORB is required to use one of the listed interfaces locally. If it fail to do so, access will be denied. The module `orber_acl` [page 165] provides operations for evaluating the access control for filters and addresses. See also the Interface Configuration [page 22] and Firewall Configuration [page 20] chapters.

**secure**
Determines the security mode Orber will use, which is either no if it is an insecure domain or the type of security mechanism used. Currently, per default, Orber is compliant with CSIv1 level 0, which means IIOP via SSL/TLS. The security chapter later in this manual describes how to get security in Orber and how the options are used.

**iiop_ssl_port**
If set, the value must be an integer greater than zero and not equal to `iiop_port`.

**iiop_ssl_backlog**
Defines the maximum length the queue of pending incoming connections may grow to.

**iiop_ssl_ip_address_local**
This option defines the default local interface Orber will use when connecting to another ORB via IIOP SSL, i.e., Orber act as the client side ORB. The value is a IPv4 or IPv6 address as a string. It is possible to override `iiop_ssl_ip_address_local` by defining `iiop_acl` or passing the Orber generic interface Context. If this option is not used, the underlying will choose which interface to use. For more information, see the Interface Configuration [page 22] section.

**nat_iiopt_ssl_port**
If set, the value must be an integer greater than zero.
Chapter 3: Installing Orber

```
ssl_server_cacertfile  the file path to a server side CA certificate.
ssl_server_certfile    The path to a file containing a chain of PEM encoded certificates.
ssl_server_verify      The type of verification used by SSL during authentication of the other peer for incoming calls.
ssl_server_depth       The SSL verification depth for outgoing calls.
ssl_server_password    The server side key string.
ssl_server_keyfile     The file path to a server side key.
ssl_server_ciphers     The server side cipher string.
ssl_server_cachetimeout The server side cache timeout.
ssl_client_cacertfile  The path to a file containing a chain of PEM encoded certificates.
ssl_client_certfile    The file path to a client side CA certificate.
ssl_client_verify      The type of verification used by SSL during authentication of the other peer for outgoing calls.
ssl_client_depth       The SSL verification depth for incoming calls.
ssl_client_password    The client side key string.
ssl_client_keyfile     The file path to a client side key.
ssl_client_ciphers     The client side cipher string.
ssl_client_cachetimeout The client side cache timeout.
```

It is possible to invoke operations using the extra timeout parameter:

```
erl> module_interface:functio(ObjRef, Timeout, ..Arguments..).
erl> module_interface:functio(ObjRef, [{timeout, Timeout}], ..Arguments..).
erl> module_interface:functio(ObjRef, ..Arguments..).
```

The extra Timeout argument will override the configuration parameter `iiop_timeout`. It is, however, not possible to use `infinity` to override the Timeout parameter. The Timeout option is also valid for objects which resides within the same Orber domain.

The `iiop_setup_connection_timeout`, `iiop_timeout`, `iiop_connection_timeout` and `iiop_in_connection_timeout` variables should be used. The specified values is implementation specific, i.e., WAN or LAN, but they should range from `iiop_setup_connection_timeout` to `iiop_connection_timeout`.

To change these settings in the configuration file, the `-config` flag must be added to the erl command. See the Reference Manual `config(4)` for further information. The values can also be sent separately as options to the Erlang node when it is started, see the Reference Manual `erl(1)` for further information.

### 3.2.1 Orber Environment Flags

The Environment Flags allows the user to activate debugging facilities or change Orber’s behavior. The latter may result in that Orber is no longer compliant with the OMG standard, which may be necessary when communicating with a non-compliant ORB.
3.2: Configuration

<table>
<thead>

</tbody>
</table>

Table 3.2: Orber Environment Flags

Any combination of the flags above may be used and changes the behavior as follows:

- **Exclude CodeSet Component** - instruct Orber to exclude the CodeSet component in exported IOR:s. When activated, no negotiating regarding character and wide character conversions between the client and the server will occur. This flag will, most likely, cause problems if your IDL specification contains the datatypes wchar and/or wstring.

- **Local Typechecking** - If activated, parameters, replies and raised exceptions will be checked to ensure that the data is correct. If an error occurs, the error_logger is used to generate reports. One MAY NOT use this option for delivered systems due to the extra overhead. Since this option activates typechecking for all objects generated on the target node, it is also possible to use the option `local_typecheck, boolean()` when invoking `oe_create/2, oe_create_link/2, corba:create/4 or corba:create_link/4`, to override the configuration parameter.

- **Use Host Name in IOR** - normally Orber inserts the IP-number in IOR:s when they are exported. In some cases, this will cause the clients to open two connections instead of one.

- **Enable NAT** - if this flag is set, it is possible to use the NAT (Network Address Translation) configuration parameters (nat_iop_port, nat_iop_ssl_port and nat_ip_address).

- **Local Interceptors** - use interceptors for local invocations.

- **Light IFR** - if the IFR is not explicitly used and this flag is set, Orber will use a minimal IFR to reduce memory usage and installation time.

- **Use IPv6** - when this option is activated, Orber will use IPv6 for inter-ORB communication.

- **EXIT Tolerance** - servers will survive even though the call-back module caused an EXIT.

- **Enable incoming ACL** - activates access control for incoming connections.

- **Enable outgoing ACL** - activates access control for outgoing connections.

- **Use Current Interface in IOR** - when set, Orber will add the interface the request came via to exported local IOR:s.

Invoking the operation orber:info/1/2 [page 155] will display the currently set flags in a readable way.
3.3 Firewall Configuration

Firewalls are used to protect objects from clients in other networks or sub-networks, but also to restrict which hosts internal objects may connect to (i.e. inbound protection and outbound protection). A firewall can limit access based on:

- Transport Level - performs access control decisions based on address information in TCP headers.
- Application Level - understands GIOP messages and the specific transport level inter-ORB Protocol supported e.g. IIOP.

This section describes how to configure a Transport Level firewall. It must have prior knowledge of the source to destination mappings, and conceptually has a configuration table containing tuples of the form: \( (\text{inhost} : \text{inport}, \text{outhost} : \text{outport}) \). If there are no port restrictions it is rather easy to configure the firewall. Otherwise, we must consider the following alternatives:

- Incoming Requests - Orber only uses the port-numbers specified by the configuration parameters `iiop_port` and `iiop_ssl_port`. Other ORB’s may use several ports but it should be possible to change this behavior. Consult the other ORBs documentation.
- Outgoing Requests - Most ORB’s, Orber included, ask the OS to supply a vacant local port when connecting to the server-side ORB. It is possible to change this behavior when using Orber (i.e. set the configuration parameter `iiop_out_ports`).

**Warning:**
Using the option `iiop_out_ports` may result in that Orber runs out of valid ports numbers. For example, other applications may steal some of the ports or the number of concurrent outgoing connections to other ORBs may be higher than expected. To reduce, but not eliminate, the risk you should use `iiop_connection_timeout`.

Firewall configuration example:

```
# "Plain" IIOP
To: Orber-IPNo:(iiop_port) From: ORB-IPNo:X
To: ORB-IPNo:Z From: Orber-IPNo:(iiop_out_ports | Any Port)

# IIOP via SSL
To: Orber-IPNo:(iiop_port) From: ORB-IPNo:X
To: Orber-IPNo:(iiop_ssl_port) From: ORB-IPNo:Y
To: ORB-IPNo:Z From: Orber-IPNo:(iiop_out_ports | Any Port)
```

If the communication take place via a TCP Firewall with NAT [page 21] (Network Address Translation), we must activate this behavior and define the external address and/or ports.
Using NAT makes it possible to use different host data for different network domains. This way we can share Internet Protocol address resources or obscure resources. To enable this feature the Enable NAT [page 18] flag must be set and nat_iio_port, nat_iio_ssl_port and nat_ip_address configured, which maps to iio_port, iio_ssl_port and ip_address respectively. Hence, the firewall must be configured to translate the external to the internal representation correctly.

If it is necessary to limit the access to an ORB within a secure network, but other applications running on the same host may not be blocked out, one can use a Application Level firewall or Orber Access Control List (ACL). The latter makes it possible for the user to define which hosts may communicate, either as server or client, with Orber. This is achieved by defining the configuration parameter iiop_acl [page 14]. The Classless Inter Domain Routing (CIDR) Filter determines which peer interfaces and ports the other ORB may use.

<table>
<thead>
<tr>
<th>Filter</th>
<th>Peer Interface(s)</th>
<th>Peer Port(s)</th>
</tr>
</thead>
<tbody>
<tr>
<td>&quot;10.1.1.1&quot;</td>
<td>10.11.1</td>
<td>any</td>
</tr>
<tr>
<td>&quot;10.1.1.1/8&quot;</td>
<td>10.0.0.0-10.255.255.255</td>
<td>any</td>
</tr>
<tr>
<td>&quot;10.1.1.1/8#4001&quot;</td>
<td>10.0.0.0-10.255.255.255</td>
<td>4001</td>
</tr>
<tr>
<td>&quot;10.1.1.1/8#4001/5001&quot;</td>
<td>10.0.0.0-10.255.255.255</td>
<td>4001-5001</td>
</tr>
</tbody>
</table>

Table 3.3: Orber ACL Filters

Orber ACL, also allows the user to define which local interface(s) may be used, but will not detect spoofing. The operation orber_acl:match/2/3 [page 165] makes it easy to verify whether access would be granted or not. For example, if Orber would be started with the ACL [{tcp_out, "10.1.1.1/8#4001/5001"}], then orber_acl:match/2 would behave as follows:

```erl
erl> orber_acl:match([{11,1,1,1}, tcp_out]).
false

erl> orber_acl:match([{10,1,1,1}, tcp_out]).
```

Orber Application 21
Chapter 3: Installing Orber

true

erl> orber_acl:match([11,1,1,1], tcp_out, true).
{false,[],0}

erl> orber_acl:match([10,1,1,1], tcp_out, true).
{true,[],{4001,5001}}

Only if the returned boolean is true the extra return values makes a difference. In the example above, {true,[],[4001,5001]} means that Orber may connect to "10.1.1.1", using any local interface, if the server-side ORB listens for incoming connect requests on a port within the range 4001-5001. Note, invoking the orber_acl:match/2/3 operation, will not result in a connect attempt by Orber. The reason for this, is that this function may be used on a live node as well as in test environment. Hence, if a local interface is currently not available or no server-side ORB available via the given host/port(s), will not be detected by Orber.

3.4 Interface Configuration

In many cases it is sufficient to simply configure the underlying OS which local interfaces shall be used for all applications. But, in some cases it is required, due to, for example, the firewall configuration, that different local interfaces are used for different applications. Some times, it is even necessary to use a specific interface for a single CORBA object. This section describe how one can alter this in different ways.

The default behavior is that Orber lets the OS configuration decide which interface will be added in IOR:s exported to another ORB and the local interface used when connecting to another ORB (Orber act as client side ORB). The latter can be overridden by setting the configuration parameters iiopssl_ipaddresslocal and/or ipaddresslocal, which will affect IIOP via SSL and IIOP respectively. These parameters can be overridden by using the Orber generic interface Context or defining an ACL (Access Control List). The latter always takes precedence if a local interface is included (e.g. [[tcp_out, "10.0.0.0/8", ["10.0.0.1"]]). If the interface is excluded (e.g. [[tcp_out, "10.0.0.0/8"]]), the interface chosen will, in the following order, be determined by #'IOP_ServiceContext', ip_addresslocal/iiop_ssl_ip_addresslocal or the configuration of the underlying system.

Adding the interface context, for generated stubs/skeletons, is done in the following way:

Ctx = #'IOP_ServiceContext'{context_id = ?ORBER_GENERIC_CTX_ID, context_data = {interface, "10.0.0.1"}}, 'CosNaming_NamingContext':resolve(NS, [{context, [Ctx]}], Name),

It is also possible to add the context to corba:string_to_object/2, corba:resolve_initial_references/2, corba:resolve_initial_references_remote/3, corba:list_initial_services_remote/2, corba:object:not_exist/2, corba:object:non_exist/2 and corba:object:is/3. The operations exported by corba:object are affected if the supplied IOR is external. The function corba:string_to_object/2 might require the interface context if a corbaloc or a corbaloc_string is passed (See the INS [page 51] chapter), while corba:resolve_initial_references_remote/3 and corba:list_initial_services_remote/2 always connect to another ORB and it might be necessary to add the context. The remaining corba operations are affected if calls are re-directed by setting the orbInitRef and/or orbDefaultInitRef configuration parameters. For more information, see the Reference Manual for each module.
Configuring which interface(s) that shall be used when exporting an IOR to another ORB, is determined by `nat_ip_address`, setting the flag 16#1000 [page 18] and `ip_address`, in that order. Orber listens for incoming connections either via all interfaces or the interface defined by `ip_address`. It is also possible to add and remove extra listen interfaces by using `orber:add_listen_interface/2/3` and `orber:remove_listen_interface/1`. In this case one should set the 16#1000 flag and avoid using NAT parameters.
Chapter 4

OMG IDL to Erlang Mapping

4.1 OMG IDL to Erlang Mapping - Overview

The purpose of OMG IDL, Interface Definition Language, mapping is to act as translator between platforms and languages. An IDL specification is supposed to describe data types, object types etc. CORBA is independent of the programming language used to construct clients or implementations. In order to use the ORB, it is necessary for programmers to know how to access ORB functionality from their programming languages. It translates different IDL constructs to a specific programming language. This chapter describes the mapping of OMG IDL constructs to the Erlang programming language.

4.2 OMG IDL Mapping Elements

A complete language mapping will allow the programmer to have access to all ORB functionality in a way that is convenient for a specified programming language. All mapping must define the following elements:

- All OMG IDL basic and constructed types
- References to constants defined in OMG IDL
- References to objects defined in OMG IDL
- Invocations of operations, including passing of parameters and receiving of results
- Exceptions, including what happens when an operation raises an exception and how the exception parameters are accessed
- Access to attributes
- Signatures for operations defined by the ORB, such as dynamic invocation interface, the object adapters etc.
- Scopes; OMG IDL has several levels of scopes, which are mapped to Erlang's two scopes.
4.3 Getting Started

To begin with, we should decide which type of objects (i.e. servers) we need and if two, or more, should export the same functionality. Let us assume that we want to create a system for DB (database) access for different kind of users. For example, anyone with a valid password may extract data, but only a few may update the DB. Usually, an application is defined within a module, and all global datatypes are defined on the top-level. To begin with we create a module and the interfaces we need:

```c
// DB IDL
#ifndef _DB_IDL_
define _DB_IDL_
// A module is simply a container
module DB {

    // An interface maps to a CORBA::Object.
    interface CommonUser {

    };

    // Inherit the Consumer interface
    interface Administrator : CommonUser {

    };

    interface Access {

    };

};
#endif
```

Since the Administrator should be able to do the same things as the CommonUser, the previous inherits from the latter. The Access interface will grant access to the DB. Now we are ready to define the functionality and data types we need. But, this requires that we know a little bit more about the OMG IDL.

**Note:**
The OMG defines a set of reserved case insensitive key-words, which may NOT be used as identifiers (e.g. module name). For more information, see Reserved Compiler Names and Keywords [page 44]

4.4 Basic OMG IDL Types

The OMG IDL mapping is strongly typed and, even if you have a good knowledge of CORBA types, it is essential to read carefully the following mapping to Erlang types.

The mapping of basic types is straightforward. Note that the OMG IDL double type is mapped to an Erlang float which does not support the full double value range.
4.5 Template OMG IDL Types and Complex Declarators

### OMG IDL basic types

<table>
<thead>
<tr>
<th>OMG IDL type</th>
<th>Erlang type</th>
<th>Note</th>
</tr>
</thead>
<tbody>
<tr>
<td>float</td>
<td>Erlang float</td>
<td></td>
</tr>
<tr>
<td>double</td>
<td>Erlang float</td>
<td>value range not supported</td>
</tr>
<tr>
<td>short</td>
<td>Erlang integer</td>
<td>-2(^{15}) .. 2(^{-15})-1</td>
</tr>
<tr>
<td>unsigned short</td>
<td>Erlang integer</td>
<td>0 .. 2(^{-16})-1</td>
</tr>
<tr>
<td>long</td>
<td>Erlang integer</td>
<td>-2(^{31}) .. 2(^{-31})-1</td>
</tr>
<tr>

<td></td>
</tr>
<tr>
<td>Object</td>
<td>Orber object reference</td>
<td>Internal Representation</td>
</tr>
<tr>
<td>void</td>
<td>Erlang atom</td>
<td>ok</td>
</tr>
</tbody>
</table>

Table 4.1: OMG IDL basic types

The **any** value is written as a record with the field typecode which contains the *Type Code* representation, see also the Type Code table [page 45], and the value field itself.

Functions with return type **void** will return the atom **ok**.

### OMG IDL Template and Complex Declarators

Constructed types all have native mappings as shown in the table below.

<table>
<thead>
<tr>
<th>Type</th>
<th>IDL code</th>
<th>Maps to</th>
<th>Erlang code</th>
</tr>
</thead>
<tbody>
<tr>
<td>string</td>
<td>typedef string S; void op(in S a);</td>
<td>Erlang string</td>
<td>ok = op(Obj, &quot;Hello World&quot;),</td>
</tr>
<tr>
<td>wstring</td>
<td>typedef wstring S; void op(in S a);</td>
<td>Erlang list of Integers</td>
<td>ok = op(Obj, &quot;Hello World&quot;),</td>
</tr>
<tr>
<td>sequence</td>
<td>typedef sequence &lt;long, 3&gt; S;</td>
<td>Erlang list</td>
<td>ok = op(Obj, [1, 2, 3]),</td>
</tr>
<tr>
<td>array</td>
<td>typedef string S[2]; void op(in S a);</td>
<td>Erlang tuple</td>
<td>ok = op(Obj, {&quot;one&quot;, &quot;two&quot;}),</td>
</tr>
<tr>
<td>fixed</td>
<td>typedef fixed&lt;3,2&gt; myFixed; void op(in myFixed a);</td>
<td>Erlang tuple</td>
<td>MF = fixed:create(3, 2, 314), ok = op(Obj, MF),</td>
</tr>
</tbody>
</table>

Table 4.2: OMG IDL Template and Complex Declarators
4.5.1 String/WString Data Types

A string consists of all possible 8-bit quantities except null. Most ORB:s uses, including Orber, the character set Latin-1 (ISO-8859-1). The wstring type is represented as a list of integers, where each integer represents a wide character. In this case Orber uses, as most other ORB:s, the UTF-16 (ISO-10646-1:1993) character set.

When defining a a string or wstring they can be of limited length or null terminated:

```c
// Null terminated
typedef string myString;
typedef wstring myWString;
// Maximum length 10
typedef string<10> myString10;
typedef wstring<10> myWString10;
```

If we want to define a char/string or wchar/wstring constant, we can use octal (\OOO - one, two or three octal digits), hexadecimal (\xHH - one or two hexadecimal digits) and unicode (\uHHHH - one, two, three or four hexadecimal digits) representation as well. For example:

```c
const string SwedensBestSoccerTeam = "\101" "\x49" "\u004B";
const wstring SwedensBestHockeyTeam = L"\101\x49\u004B";
const char aChar = '\u004B';
const wchar aWchar = L'\u004C';
```

Naturally, we can use "Erlang", L"Rocks", 'A' and L'A' as well.

4.5.2 Sequence Data Type

A sequence can be defined to be of a maximum length or unbounded, and may contain Basic and Template types and scoped names:

```c
typedef sequence <short, 1> aShortSequence;
typedef sequence <long> aLongSequence;
typedef sequence <aLongSequence> anEvenLongerSequence;
```

4.5.3 Array Data Type

Arrays are multidimensional, fixed-size arrays. The indices is language mapping specific, which is why one should not pass them as arguments to another ORB.

```c
typedef long myMatrix[2][3];
```
4.5.4 Fixed Data Type

A Fixed Point literal consists of an integer part (decimal digits), decimal point and a fraction part (decimal digits), followed by a D or d. Either the integer part or the fraction part may be missing; the decimal point may be missing, but not d/D. The integer part must be a positive integer less than 32. The Fraction part must be a positive integer less than or equal to the Integer part.

```cpp
const fixed myFixed1 = 3.14D;
const fixed myFixed2 = .14D;
const fixed myFixed3 = 0.14D;
const fixed myFixed4 = 3.D;
const fixed myFixed5 = 3D;
```

It is also possible to use unary (+) and binary (+-*/) operators:

```cpp
const fixed myFixed6 = 3D + 0.14D;
const fixed myFixed7 = -3.14D;
```

The Fixed Point examples above are, so called, anonymous definitions. In later CORBA specifications these have been deprecated as function parameters or return values. Hence, we strongly recommend that you do not use them. Instead, you should use:

```cpp
typedef fixed<5,3> myFixed53;
const myFixed53 myFixed53constant = 03.140d;
typedef fixed<3,2> myFixed32;
const myFixed32 myFixed32constant = 3.14d;
```

```cpp
myFixed53 foo(in myFixed32 MF); // OK
void bar(in fixed<5,3> MF); // Illegal
```

For more information, see Fixed [page 144] in Orber's Reference Manual.

Now we continue to work on our IDL specification. To begin with, we want to limit the size of the logon parameters (Id and password). Since the UserID and Password parameters, only will be used when invoking operations on the Access interface, we may choose to define them within the scope that interface. To keep it simple our DB will contain employee information. Hence, as the DB key we choose an integer (EmployeeNo).

```cpp
// DB IDL
#ifndef _DB_IDL_
#define _DB_IDL_

module DB {

typedef unsigned long EmployeeNo;

interface CommonUser {
    any lookup(in EmployeeNo ENo);
};

interface Administrator : CommonUser {
```
void delete(in EmployeeNo ENo);

};

interface Access {

typedef string<10> UserID;
typedef string<10> Password;

CommonUser logon(in UserID ID, in Password PW);

};

};
#endif

But what should, for example, the lookup operation return? One option is to use the any data type. But, depending on what kind of data it encapsulates, this datatype can be rather expensive to use. We might find a solution to our problems among the Constructed IDL types.

### 4.6 Constructed OMG IDL Types

Constructed types all have native mappings as shown in the table below.

<table>
<thead>
<tr>
<th>Type</th>
<th>IDL code</th>
<th>Maps to</th>
<th>Erlang code</th>
</tr>
</thead>
<tbody>
<tr>
<td>struct</td>
<td>struct myStruct { long a; short b; }; void op(in myStruct a);</td>
<td>Erlang record</td>
<td>ok = op(Obj, #myStruct{a=300, b=127}),</td>
</tr>
<tr>
<td>union</td>
<td>union myUnion switch(long) { case 1: long a; }; void op(in myUnion a);</td>
<td>Erlang record</td>
<td>ok = op(Obj, #myUnion{label=1, value=66}),</td>
</tr>
<tr>
<td>enum</td>
<td>enum myEnum {one, two}; void op(in myEnum a);</td>
<td>Erlang atom</td>
<td>ok = op(Obj, one),</td>
</tr>
</tbody>
</table>

Table 4.3: OMG IDL constructed types

### 4.6.1 Struct Data Type

A struct may have Basic, Template, Scoped Names and Constructed types as members.

### 4.6.2 Enum Data Type

The maximum number of identifiers which may defined in an enumeration is 2. The order in which the identifiers are named in the specification of an enumeration defines the relative order of the identifiers.
### 4.6.3 Union Data Type

A union may consist of:

- Identifier
- Switch - may be an integer, char, boolean, enum or scoped name.
- Body - with or without a default case; may appear at most once.

A case label must match the defined type of the discriminator, and may only contain a default case if the values given in the non-default labels do not cover the entire range of the union's discriminant type. For example:

```erlang
// Illegal default; all cases covered by // non-default cases.
union BooleanUnion switch(boolean) {
    case TRUE: long TrueValue;
    case FALSE: long FalseValue;
    default: long DefaultValue;
};
// OK
union BooleanUnion2 switch(boolean) {
    case TRUE: long TrueValue;
    default: long DefaultValue;
};
```

It is not necessary to list all possible values of the union discriminator in the body. Hence, the value of a union is the value of the discriminator and, in given order, one of the following:

1. If the discriminator match a label, explicitly listed in a case statement, the value must be of the same type.
2. If the union contains a default label, the value must match the type of the default label.
3. No value. Orber then inserts the Erlang atom `undefined` in the value field when receiving a union from an external ORB.

The above can be summed up to:

```erlang
// If the discriminator equals 1 or 2 the value // is a long. Otherwise, the atom undefined.
union LongUnion switch(long) {
    case 1:
    case 2: long TrueValue;
};
// If the discriminator equals 1 or 2 the value // is a long. Otherwise, a boolean.
union LongUnion2 switch(long) {
    case 1:
    case 2: long TrueValue;
    default: boolean DefaultValue;
};
```
Chapter 4: OMG IDL to Erlang Mapping

Warning:
Every field in, for example, a struct must be initiated. Otherwise it will be set to the atom undefined, which Orber cannot encode when communicating via IIOP. In the example above, invoking the operation with #myStruct\{a=300\} will fail (equal to #myStruct\{a=300, b=undefined\})

Now we can continue to work on our IDL specification. To begin with, we should determine the return value of the lookup operation. Since the any type can be rather expensive we can use a struct or a union instead. If we intend to return the same information about a employee every time we can use a struct. Let us assume that the DB contains the name, address, employee number and department.

// DB IDL
#ifndef _DB_IDL_
#define _DB_IDL_
module DB {

typedef unsigned long EmployeeNo;

enum Department {Department1, Department2};

struct employee {
    EmployeeNo No;
    string Name;
    string Address;
    Department Dpt;
};

typedef employee EmployeeData;

interface CommonUser {
    EmployeeData lookup(in EmployeeNo ENo);
};

interface Administrator : CommonUser {
    void delete(in EmployeeNo ENo);
};

interface Access {
    typedef string<10> UserID;
    typedef string<10> Password;

    // Since Administrator inherits from CommonUser
    // the returned Object can be of either type.
    CommonUser logon(in UserID ID, in Password PW);
};
We can also define exceptions (i.e. not system exception) thrown by each interface. Since exceptions are thoroughly described in the chapter System and User Defined Exceptions [page 75], we choose not to. Hence, we are now ready to compile our IDL-file by invoking:

```
$ erlc DB.idl
```

or:

```
$ erl
Erlang (BEAM) emulator version 5.1.1 [threads:0]
Eshell V5.1.1 (abort with ^G)
1> ic:gen('DB').
ok
2> halt().
```

The next step is to implement our servers. But, to be able to do that, we need to know how we can access data type definitions. For example, since a struct is mapped to an Erlang record we must include an hrl-file in our callback module.

### 4.7 Scoped Names and Generated Files

#### 4.7.1 Scoped Names

Within a scope all identifiers must be unique. The following kinds of definitions form scopes in the OMG IDL:

- module
- interface
- operation
- valuetype
- struct
- union
- exception

For example, since enumerants do not form a scope, the following IDL code is not valid:

```idl
module MyModule {
    // 'two' is not unique
    enum MyEnum {one, two};
    enum MyOtherEnum {two, three};
};
```
Chapter 4: OMG IDL to Erlang Mapping

But, since Erlang only has two levels of scope, module and function, the OMG IDL scope is mapped as follows:

- Function Scope - used for constants, operations and attributes
- Erlang Module Scope - the Erlang module scope handles the remaining OMG IDL scopes.

An Erlang module, corresponding to an IDL global name, is derived by converting occurrences of "::" to underscore, and eliminating the leading "::". Hence, accessing MyEnum from another module, one use MyModule::MyEnum

For example, an operation foo defined in interface I, which is defined in module M, would be written in IDL as M::I::foo and as 'M\_I':foo in Erlang - foo is the function name and 'M\_I' is the name of the Erlang module. Applying this knowledge to a stripped version of the DB.idl gives:

// DB IDL
ifndef _DB_IDL_
define _DB_IDL_
++ topmost scope ++
IC generates oe_XX.erl and oe_XX.hrl.
XX is equal to the name of the IDL-file.
Tips: create one IDL-file for each top module
and give the file the same name (DB.idl).
The oe_XX.erl module is used to register data
in the IFR.
module DB {

++ Module scope ++
To access 'EmployeeNo' from another scope, use:
DB::EmployeeNo, DB::Access etc.
typedef unsigned long EmployeeNo;

enum Department {Department1, Department2};

Definitions of this struct is contained in:
DB.hrl
Access functions exported by:
DB_employee.erl
struct employee {
... CUT ...
};
typedef employee EmployeeData;

... CUT ...

If this interface should inherit an interface
in another module (e.g. OtherModule) use:
interface Access : OtherModule::OtherInterface
interface Access {

++ interface scope ++
Types within this scope is accessible via:
DB::Access::UserID
The Stub/Skeleton for this interface is
typedef string<10> UserID;
typedef string<10> Password;

// Since Administrator inherits from CommonUser
// the returned Object can be of either type.
// This operation is exported from:
// DB_Access.erl
CommonUser logon(in UserID ID, in Password PW);

Using underscores in IDL names can lead to ambiguities due to the name mapping described above. It is advisable to avoid the use of underscores in identifiers. For example, the following definition would generate two structures named \texttt{x\_y\_z}.

module x {
    struct y_z {
        ...
    }
    interface y {
        struct z {
            ...
        }
    }
}

### 4.7.2 Generated Files

Several files can be generated for each scope.

- An Erlang source code file (*.erl*) is generated for top level scope as well as the Erlang header file.
- An Erlang header file (*.hrl*) will be generated for each scope. The header file will contain record definitions for all \texttt{struct}, \texttt{union} and \texttt{exception} types in that scope.
- Modules that contain at least one constant definition, will produce Erlang source code files (*.erl*). That Erlang file will contain constant functions for that scope. Modules that contain no constant definitions are considered empty and no code will be produced for them, but only for their included modules/interfaces.
- Interfaces will produce Erlang source code files (*.erl*), this code will contain all operation stub code and implementation functions.
- In addition to the scope-related files, an Erlang source file will be generated for each definition of the types \texttt{struct}, \texttt{union} and \texttt{exception} (these are the types that will be represented in Erlang as records). This file will contain special access functions for that record.
The top level scope will produce two files, one header file (.hrl) and one Erlang source file (.erl). These files are named as the IDL file, prefixed with oe_.

After compiling DB.idl, the following files have been generated:

- oe_DB.hrl and oe_DB.erl for the top scope level.
- DB.hrl for the module DB.
- DB_Access.hrl and DB_Access.erl for the interface DB_Access.
- DB_Administrator.hrl and DB_Administrator.erl for the interface DB_Administrator.
- DB_employee.erl for the structure employee in module DB.

Since the employee struct is defined in the top level scope, the Erlang record definition is found in DB.hrl. IC also generates stubs/skeletons (e.g. DB_CommonUser.erl) and access functions for some datatypes (e.g. DB_employee.erl). How the stubs/skeletons are used is thoroughly described in Stubs/Skeletons [page 68] and Module Interface [page 126].

### 4.8 Typecode, Identity and Name Access Functions

As mentioned in a previous section, struct, union and exception types yield record definitions and access code for that record. For struct, union, exception, array and sequence types, a special file is generated that holds access functions for TypeCode, Identity and Name. These functions are put in the file corresponding to the scope where they are defined. For example, the module DB_employee.erl, representing the employee struct, exports the following functions:

- tc/0 - returns the type code for the struct.
- id/0 - returns the IFR identity of the struct. In this case the returned value is "IDL:DB/employee:1.0", but if the struct was defined in the scope of CommonUser, the result would be "IDL:DB/CommonUser/employee:1.0". However, the user usually do not need to know the Id, just which Erlang module contains the correct Id.
- name/0 - returns the scoped name of the struct. The employee struct name is "DB_employee".

Type Codes are, for example, used in Any [page 132] values. Hence, we can encapsulate the employee struct in an any type by:

```erlang
%% Erlang code
....
AnEmployee = #'DB_employee'{'No' = 1,
                         'Name' = "Adam Ivan Kendall",
                         'Address' = "Rasunda, Solna",
                         'Dpt' = 'Department1'},
EmployeeTC = 'DB_employee':tc(),
EmployeeAny = any:create(EmployeeTC, AnEmployee),
....
```

For more information, see the Type Code listing [page 45].
4.9 References to Constants

Constants are generated as Erlang functions and are accessed by a single function call. The functions are put in the file corresponding to the scope where they are defined. There is no need for an object to be started to access a constant.

Example:

```erlang
// m.idl
module m {
    const float pi = 3.14;

    interface i {
        const float pi = 3.1415;
    };
};
```

Since the two constants are defined in different scopes, the IDL code above is valid, but not necessarily a good approach. After compiling `m.idl`, the constant definitions can be extracted by invoking:

```
$ erlc m.idl
$ erlc m.erl
$ erl
Erlang (BEAM) emulator version 5.1.1 [threads:0]
```

Eshell V5.1.1 (abort with ^G)
```
1> m:pi().
3.14000
2> m:i:pi().
3.14150
3> halt().
```

4.10 References to Objects Defined in OMG IDL

Objects are accessed by object references. An object reference is an opaque Erlang term created and maintained by the ORB.

Objects are implemented by providing implementations for all operations and attributes of the Object, see operation implementation [page 38].

4.11 Exceptions

Exceptions are handled as Erlang catch and throws. Exceptions are translated to messages over an IIOP bridge but converted back to a throw on the receiving side. Object implementations that invoke operations on other objects must be aware of the possibility of a non-local return. This includes invocation of ORB and IFR services. See also the Exceptions [page 75] section.

Exception parameters are mapped as an Erlang record and accessed as such.

An object implementation that raises an exception will use the `corba:raise/1` function, passing the exception record as parameter.
4.12 Access to Attributes

Attributes are accessed through their access functions. An attribute implicitly defines the \_get and \_set operations. These operations are handled in the same way as normal operations. The \_get operation is defined as a readonly attribute.

```plaintext
readonly attribute long RAttribute;
attribute long RWAttribute;
```

The `RAttribute` requires that you implement, in your call-back module, `get_RAttribute`. For the `RWAttribute` it is necessary to implement `get_RWAttribute` and `set_RWAttribute`.

4.13 Invocations of Operations

A standard Erlang \texttt{gen_server} behavior is used for object implementation. The \texttt{gen_server} state is then used as the object internal state. Implementation of the object function is achieved by implementing its methods and attribute operations. These functions will usually have the internal state as their first parameter, followed by any \texttt{in} and \texttt{inout} parameters.

Do not confuse the object internal state with its object reference. The object internal state is an Erlang term which has a format defined by the user.

\textbf{Note:}

It is is not always the case that the internal state will be the first parameter, as stubs can use their own object reference as the first parameter (see the IC documentation).

A function call will invoke an operation. The first parameter of the function should be the object reference and then all \texttt{in} and \texttt{inout} parameters follow in the same order as specified in the IDL specification. The result will be a return value unless the function has \texttt{inout} or \texttt{out} parameters specified; in which case, a tuple of the return value, followed by the parameters will be returned.

Example:

```plaintext
// IDL
module m {
    interface i {
        readonly attribute long RAttribute;
        attribute long RWAttribute;
        long foo(in short a);
        long bar(in char c, inout string s, out long count);
        void baz(out long Id);
    };
}
```

Is used in Erlang as:
% Erlang code
....
Obj = ...  %% get object reference
RAAttr = m_i:'_get_RAttribute'(Obj),
RWAttr = m_i:'_get_RWAttribute'(Obj),
ok = m_i:'_set_RWAttribute'(Obj, Long),
R1 = m_i:foo(Obj, 55),
{R2, S, Count} = m_i:bar(Obj, $a, "hello"),
....

Note how the inout parameter is passed and returned. There is no way to use a single occurrence of a variable for this in Erlang. Also note, that ok, Orber's representation of the IDL-type void, must be returned by baz and '_set_RWAttribute'. These operations can be implemented in the call-back module as:

'_set_RWAttribute'(State, Long) ->
    {reply, ok, State}.

'_get_RWAttribute'(State) ->
    {reply, Long, State}.

'_get_RAttribute'(State) ->
    {reply, Long, State}.

foo(State, AShort) ->
    {reply, ALong, State}.

bar(State, AShort, AString) ->
    {reply, {ALong, "MyString", ALong}, State}.

baz(State) ->
    {reply, {ok, AId}, State}.

The operations may require more arguments (depends on IC options used). For more information, see Stubs/Skeletons [page 68] and Module Interface [page 126].

**Warning:**
A function can also be defined to be oneway, i.e. asynchronous. But, since the behavior of a oneway operation is not defined in the OMG specifications (i.e. the behavior can differ depending on which other ORB Orber is communicating with), one should avoid using it.

### 4.14 Implementing the DB Application

Now we are ready to implement the call-back modules. There are three modules we must create:

- DB_Access_impl.erl
- DB_CommonUser_impl.erl
- DB_Administrator_impl.erl
An easy way to accomplish that, is to use the IC backend erl_template, which will generate a complete call-back module. One should also add the same compile options, for example this or from, used when generating the stub/skeleton modules:

```
$> erlc +"{be,erl_template}" DB.idl
```

We begin with implementing the DB_Access_impl.erl module, which, if we used erl_template, will look like the following. All we need to do is to add the logic to the logon operation.

```erlang
%%----------------------------------------------------------------------
%% <LICENSE>
%%
%% $Id$
%%
%%----------------------------------------------------------------------
%% Module : DB_Access_impl.erl
%%
%% Source : /home/user/example/DB.idl
%%
%% Description :
%%
%% Creation date: 2005-05-20
%%
%%----------------------------------------------------------------------
-module('DB_Access_impl').
-export([logon/3]).

%%----------------------------------------------------------------------
%% Internal Exports
%%----------------------------------------------------------------------
-export([init/1,
        terminate/2,
        code_change/3,
        handle_info/2]).

%%----------------------------------------------------------------------
%% Include Files
%%----------------------------------------------------------------------

%%----------------------------------------------------------------------
%% Macros
%%----------------------------------------------------------------------

%%----------------------------------------------------------------------
%% Records
%%----------------------------------------------------------------------
-record(state, {}).

%%----------------------------------------------------------------------
%% API Functions
```
logon(State, ID, PW) ->
    OE_Reply = case check_user(ID, PW) of
        {ok, administrator} ->
            'DB_Administrator':oe_create();
        {ok, common} ->
            'DB_CommonUser':oe_create();
        error ->
            %% Here we should throw an exception
            corba:raise(...)
    end,
    {reply, OE_Reply, State}.
%% Function : code_change/3
%% Arguments : OldVsn = undefined | term()
%% State = NewState = term()
%% Extra = term()
%% Returns : {ok, NewState}
%% Raises : -
%% Description: Invoked when the object should update its internal state
due to code replacement.

code_change(_OldVsn, State, _Extra) ->
    {ok, State}.

%% Function : handle_info/2
%% Arguments : Info = normal | shutdown | term()
%% State = NewState = term()
%% Returns : {noreply, NewState} | {noreply, NewState, Timeout} |
%% {stop, Reason, NewState}
%% Raises : -
%% Description: Invoked when, for example, the server traps exits.

handle_info(_Info, State) ->
    {noreply, State}.

Since DB_Administrator inherits from DB_CommonUser, we must implement delete in the
DB_Administrator_impl.erl module, and lookup in DB_Administrator_impl.erl and
DB_CommonUser_impl.erl. But wait, is that really necessary? Actually, it is not. We simple use the IC
compile option impl:

$ erlc +'{{impl, "DB::CommonUser"}, "DBUser_impl"}'+
$ erlc *.erl

Instead of creating, and not the least, maintaining two call-back modules, we only have to deal with
DBUser_impl.erl. If we generated the templates, we simply rename DB_Administrator_impl.erl to
DBUser_impl.erl. See also the Exceptions [page 75] chapter. In the following example, only the
implementation of the API functions are shown:

%% API Functions
%% Function : delete/2
%% Arguments : State - term()
%% ENo = unsigned_Long()
%% Returns : ReturnValue = ok
%% Raises : -

42

Orber Application
### 4.14: Implementing the DB Application

#### delete:

```erlang
delete(State, ENo) ->
    %% How we access the DB, for example mnesia, is not shown here.
    case delete_employee(No) of
        ok ->
            {reply, ok, State};
        error ->
            %% Here we should throw an exception if
            %% there is no match.
            corba:raise(....)
    end.
```

#### lookup:

```erlang
lookup(State, ENo) ->
    %% How we access the DB, for example mnesia, is not shown here.
    case lookup_employee(ENo) of
        %% We assume that we receive a 'DB_employee' struct
        {ok, Employee} ->
            OE_Reply = Employee,
            {reply, OE_Reply, State};
        error ->
            %% Here we should throw an exception if
            %% there is no match.
            corba:raise(....)
    end.
```

After you have compiled both call-back modules, and implemented the missing functionality (e.g. `lookup_employee/1`), we can test our application:

```
%% Erlang code
....
%% Create an Access object
Acc = 'DB_Access':oe_create(),

%% Login is Common user and Administrator
Adm = 'DB_Access':logon(A, "admin", "pw"),
Com = 'DB_Access':logon(A, "comm", "pw"),

%% Lookup existing employee
```

Orber Application
Employee = 'DB_Administrator':lookup(Adm, 1),
Employee = 'DB_CommonUser':lookup(Adm, 1),

%% If we try the same using the DB_CommonUser interface
%% it result in an exit since that operation is not exported.
{'EXIT', _} = (catch 'DB_CommonUser':delete(Adm, 1)),

%% Try to delete the employee via the CommonUser Object
{'EXCEPTION', _} = (catch 'DB_Administrator':delete(Com, 1)),

%% Invoke delete operation on the Administrator object
ok = 'DB_Administrator':delete(Adm, 1),
....

4.15 Reserved Compiler Names and Keywords

The use of some names is strongly discouraged due to ambiguities. However, the use of some names is prohibited when using the Erlang mapping, as they are strictly reserved for IC.

IC reserves all identifiers starting with OE and oe for internal use.
Note also, that an identifier in IDL can contain alphabetic, digits and underscore characters, but the first character must be alphabetic.

The OMG defines a set of reserved words, shown below, for use as keywords. These may not be used as, for example, identifiers. The keywords which are not in bold face was introduced in the OMG CORBA-3.0 specification.

<table>
<thead>
<tr>
<th>abstract</th>
<th>exception</th>
<th>inout</th>
<th>provides</th>
<th>truncatable</th>
</tr>
</thead>
<tbody>
<tr>
<td>any</td>
<td>emits</td>

</tr>
<tr>
<td>double</td>
<td>in</td>
<td>private</td>
<td>TRUE</td>
<td></td>
</tr>
</tbody>
</table>

Table 4.4: OMG IDL keywords

The keywords listed above must be written exactly as shown. Any usage of identifiers that collide with a keyword is illegal. For example, long is a valid keyword; Long and LONG are illegal as keywords and identifiers. But, since the OMG must be able to expand the IDL grammar, it is possible to use Escaped Identifiers. For example, it is not unlikely that native have been used in IDL-specifications as identifiers.
One option is to change all occurrences to `myNative`. Usually, it is necessary to change programming language code that depends upon that IDL as well. Since Escaped Identifiers just disable type checking (i.e., if it is a reserved word or not) and leaves everything else unchanged, it is only necessary to update the IDL-specification. To escape an identifier, simply prefix it with `_;`. The following IDL-code is illegal:

```idl
typedef string native;
interface i {
    void foo(in native Arg);
};
```

With Escaped Identifiers the code will look like:

```idl
typedef string _native;
interface i {
    void foo(in _native Arg);
};
```

### 4.16 Type Code Representation

Type Codes are used in any values. To avoid mistakes, you should use access functions exported by the Data Types modules (e.g., struct, union etc) or the `orber_tc [page 183]` module.

<table>
<thead>
<tr>
<th>Type Code</th>
<th>Example</th>
</tr>
</thead>
<tbody>
<tr>
<td>tknull</td>
<td></td>
</tr>
<tr>
<td>tkvoid</td>
<td></td>
</tr>
<tr>
<td>tkshort</td>
<td></td>
</tr>
<tr>
<td>tklong</td>
<td></td>

CosNaming Service

5.1 Overview of the CosNaming Service

The CosNaming Service is a service developed to help users and programmers identify objects by human readable names rather than by a reference. By binding a name to a naming context (another object), a contextual reference is formed. This is helpful when navigating in the object space. In addition, identifying objects by name allows you to evolve and/or relocate objects without client code modification.

The CosNaming service has some concepts that are important:

- name binding - a name to object association.
- naming context - is an object that contains a set of name bindings in which each name is unique. Different names can be bound to the same object.
- to bind a name - is to create a name binding in a given context.
- to resolve a name - is to determine the object associated with the name in a given context.

A name is always resolved in a context, there no absolute names exist. Because a context is like any other object, it can also be bound to a name in a naming context. This will result in a naming graph (a directive graph with notes and labeled edges). The graph allows more complex names to refer to an object. Given a context, you can use a sequence to reference an object. This sequence is henceforth referred to as name and the individual elements in the sequence as name components. All but the last name component are bound to naming contexts.

The diagram in figure 1 illustrates how the Naming Service provides a contextual relationship between objects, NamingContexts and NameBindings to create an object locality, as the object itself, has no name.
The naming contexts provide a directory of contextual reference and naming for objects (an object can appear to have more than one name). In figure 1 the object to the right can either be called \texttt{alpha} from one context or \texttt{gamma} from another.
The Naming Service has an initial naming context, which is shown in the diagram as the top-most object in the naming graph. It has two names beta and epsilon, which are bound to other naming contexts. The initial naming context is a well-known location used to share a common name space between multiple programs. You can traverse the naming graph until you reach a name, which is bound to an object, which is not a naming context.

We recommend reading chapter 12, CORBA Fundamentals and Programming, for detailed information regarding the Naming Service.

5.2 The Basic Use-cases of the Naming Service

The basic use-cases of the Naming Service are:

- Fetch initial reference to the naming service.
- Creating a naming context.
- Binding and unbinding names to objects.
- Resolving a name to an object.
- Listing the bindings of a naming context.
- Destroying a naming context.

5.2.1 Fetch Initial Reference to the Naming Service

In order to use the naming service you have to fetch an initial reference to it. This is done with:

```
NS = corba:resolve_initial_reference("NameService").
```

**Note:**

NS in the other use-cases refers to this initial reference.

5.2.2 Creating a Naming Context

There are two functions for creating a naming context. The first function, which only creates a naming context object is:

```
NC = 'CosNaming_NamingContext':new_context(NS).
```

The other function creates a naming context and binds it to a name in an already existing naming context (the initial context in this example):

```
NC = 'CosNaming_NamingContext':bind_new_context(NS, lname:new(["new"])).
```
Chapter 5: CosNaming Service

5.2.3 Binding and Unbinding Names to Objects

The following steps illustrate how to bind/unbind an object reference to/from a name. For the example below, assume that the NamingContexts in the path are already bound to the name /workgroup/services, and that reference to the services context are in the variable Sc.

1. Use the naming library functions to create a name
   \[ \text{Name} = \text{lname}:\text{new}(["object"]) \].
2. Use CosNaming::NamingContext::bind() to bind a name to an object
   \[ \text{CosNaming_NamingContext}:\text{bind}(\text{Sc}, \text{Name}, \text{Object}) \].
3. Use CosNaming::NamingContext::unbind() to remove the NameBinding from an object
   \[ \text{CosNaming_NamingContext}:\text{unbind}(\text{Sc}, \text{Name}) \].

**Note:**

Objects can have more than one name, to indicate different paths to the same object.

5.2.4 Resolving a Name to an Object

The following steps show how to retrieve the object reference to the service context above (/workgroup/services).

1. Use the naming library functions to create a name path:
   \[ \text{Name} = \text{lname}:\text{new}(["workgroup", "services"]) \].
2. Use CosNaming::NamingContext::resolve() to to resolve the name to an object
   \[ \text{Sc} = \text{CosNaming_NamingContext}:\text{resolve}(\text{NS}, \text{Name}) \].
   An alternative is to use:
   \[ \text{Sc} = \text{corba}:\text{string_to_object}(\text{"corbaname:rir:/NameService#workgroup/services/"}) \].
   The corbaname schema is described further in the Interoperable Naming Service section.

5.2.5 Listing the Bindings in a NamingContext

1. Use CosNaming::NamingContext::list() to list all the bindings in a context
   The following code retrieves and lists up to 10 bindings from a context.
   \[ \{\text{BList, BIterator}\} = \text{CosNaming_NamingContext}:\text{list}(\text{Sc}, 10) \].
   \[ \text{lists}:\text{foreach}(\text{fun}({\{\text{Id, Kind}, \text{BindingType}\}} \rightarrow \text{case BindingType of}
   \begin{align*}
   & \text{nobject} -> \text{io:format}(\text{"id: \%s, kind: \%s, type: object\-n", [\text{Id, Kind}]})
   \end{align*}
   \]
5.3 Interoperable Naming Service

### Note:
Normally a BindingIterator is helpful in situations where you have a large number of objects in a list, as the programmer then can traverse it more easily. In Erlang it is not needed, because lists are easily handled in the language itself.

### Warning:
Remember that the BindingIterator (BIterator in the example) is an object and therefore must be removed otherwise dangling processes will occur. Use `CosNaming::BindingIterator::destroy()` to remove it.

```
'CosNaming_NamingContext':destroy(BIterator).
```

5.2.6 Destroying a Naming Context

The naming contexts are persistent and must be explicitly removed. (they are also removed if all Orber nodes in the domain are stopped).

1. Use `CosNaming::NamingContext::destroy()` to remove a NamingContext

```
'CosNaming_NamingContext':destroy(Sc).
```

5.3 Interoperable Naming Service

The OMG specifies URL schemes, which represent a CORBA object and a CORBA object bound in a NamingContext, for resolving references from other ORB:s. As of today, three schemes are defined:

- IOR
- corbaloc
- corbaname

5.3.1 IOR

A stringified IOR is a valid URL format but difficult for humans to handle through non-electronic means. This URL format does not depend on a specific Name Service and, thus, is robust and insulates the client from the encapsulated transport information and object key used to reference the object.
Chapter 5: CosNaming Service

5.3.2 corbaloc

The notation of this scheme is similar to the more well known URL http, and the full corbaloc BNF is:

```plaintext
<corbaloc> = "corbaloc:"<obj_addr_list>[/"<key_string>"]
<obj_addr_list> = ["<obj_addr>","]*<obj_addr>
<obj_addr> = <prot_addr> | <future_prot_addr>
<prot_addr> = <rir_prot_addr> | <iiop_prot_addr>
<rir_prot_addr> = <rir_prot_token>:"n"
<future_prot_addr> = <future_prot_id><future_prot_addr>
<future_prot_id> = <future_prot_token>:"n"
<iio_prot_addr> = <iio_id><iio_addr>
<iio_id> = <iio_default> | <iio_prot_token>:"n"
<iio_default> = "n"
<iio_prot_token> = "iio"
<iio_addr> = <version><host>[:"<port>"]
<host> = DNS-style Host Name | ip_address
<version> = <major>"."<minor>"@" | empty_string
<port> = number
<major> = number
<minor> = number
<key_string> = for example NameService
```

The corbaloc scheme consists of 3 parts:

- **Protocol** - as of today iiop or rir is supported. Using rir means that we will resolve the given Key locally, i.e., the same as using corba:resolve_initial_references("NameService").
- **IIOP address** - this address can be divided into Version, Host and Port. If the version or port are left out they will be set to the default values 1.0 and 2809 respectively.
- **KeyString** - an object key, e.g., "NameService". If no Key is supplied the default value "NameService" will be used.

A corbaloc can be passed used together with corba:resolve_initial_references("corbaloc::1.0@erlang.org:1001/NameService") or set as the configuration variables orbInitilRef or orbDefaultInitilRef and calling corba:resolve_initial_references("NameService"). For more information see the Orber installation chapter. corbaloc can also be used together with corbaname to gain an easy access to a Name Service.

Currently, the OMG defines a set of reserved keys and the type of object, listed below, they should be associated with. The NameService key may not be changed in Orber. If you want to add one of the reserved keys as an initial service, simply use:

```erlang
1> Factory = cosNotificationApp:start_global_factory().
2> corba:add_initial_service("NotificationService", Factory).
```

This object can then be easily resolved by any other ORB, supporting the Interoperable Naming Service, by using:

```erlang
3> NF = corba:string_to_object("corbaloc::1.0@erlang.org:4001/NotificationService").
```
5.3: Interoperable Naming Service

<table>
<thead>
<tr>
<th>String Name</th>
<th>Object Type</th>
</tr>
</thead>
<tbody>
<tr>

</tr>
<tr>
<td>CodecFactory</td>
<td>IOP::CodecFactory</td>
</tr>
<tr>
<td>PICurrent</td>
<td>PortableInterceptors::Current</td>
</tr>
</tbody>
</table>

Table 5.1: Currently reserved key strings

5.3.3 corbaname

The corbaname URL scheme is an extension of the corbaloc scheme, and the full corbaname BNF is:

```
corbaname = "corbaname:"
<obj_addr_list> = as described above.
<key_string> = as described above.
```

The string name, concatenated to the corbaloc string, identifies a binding in a naming context. A name component consists of two parts, i.e., id and kind, which is represented as follows:

<table>
<thead>
<tr>
<th>String Name</th>
<th>Name Sequence</th>
<th>Comment</th>
</tr>
</thead>
<tbody>
<tr>
<td>&quot;id1//id3.kind3&quot;</td>
<td>{&quot;id1&quot;,&quot;&quot;,{&quot;id3&quot;,&quot;kind3&quot;}}</td>
<td>The first component has no kind defined while the second component's both fields are empty.</td>
</tr>
<tr>
<td>&quot;id1//id3.kind3&quot;</td>
<td>ERROR</td>
<td>Not allowed, must insert a '.' between the '//'.</td>
</tr>
<tr>
<td>&quot;id1.kind1/.&quot;</td>
<td>{&quot;id1&quot;,&quot;kind1&quot;},{&quot;&quot;,&quot;&quot;}</td>
<td>The first component's fields are both set while the second component's both fields are empty.</td>
</tr>
<tr>
<td>&quot;id1.kind1/id2.&quot;</td>
<td>ERROR</td>
<td>An Id with a trailing '.' is not allowed.</td>
</tr>
<tr>
<td>&quot;i\d1//i\d2&quot;</td>
<td>{&quot;i\d1&quot;,&quot;&quot;,{&quot;i\d2&quot;,&quot;&quot;}}</td>
<td>Since '.' and '/' are used to separate the components, these tokens must be escaped to be correctly converted.</td>
</tr>
</tbody>
</table>

Table 5.2: Stringified Name representation

After creating a stringified Name we can either use:
Chapter 5: CosNaming Service

NameStr = "org.erlang",
NS = corba:resolve_initial_references("NameService"),
Obj = 'CosNaming_NamingContextExt':resolve_str(NS, NameStr),

or concatenate the Name String using:

NameStr = "Swedish/Soccer/Champions",
Address = "corbaname:iiop:1.0@www.aik.se:2000/NameService",
NS = corba:resolve_initial_references("NameService"),
URLStr = 'CosNaming_NamingContextExt':to_url(NS, Address, NameStr),
Obj = corba:string_to_object(URLStr),

Using the first alternative, the configuration variables orbInitilRef and orbDefaultInitilRef, will determine which other ORB's or the local Name Service Orber will try to resolve the given string from. The second alternative allows us to override any settings of the configuration variables.

The function to_url/3 will perform any necessary escapes compliant with IETF/RFC 2396. US-ASCII alphanumeric characters and "," | "/" | ":" | ";" | ";" | ":" | ";" | ":" | ";" | ";" | ";" | ";" | ";" are not escaped.
Chapter 6

How to use security in Orber

6.1 Security in Orber

6.1.1 Introduction

Orber SSL provides authentication, privacy and integrity for your Erlang applications. Based on the Secure Sockets Layer protocol, the Orber SSL ensures that your Orber clients and servers can communicate securely over any network. This is done by tunneling IIOP through an SSL connection. To get the node secure you will also need to have a firewall which only lets through connections to certain ports.

6.1.2 Enable Usage of Secure Connections

To enable a secure Orber domain you have to set the configuration variable `secure` which currently only can have one of two values; `no` if no security for IIOP should be used and `ssl` if secure connections is needed (`ssl` is currently the only supported security mechanism).

The default is no security.

Setting of a CA certificate file with an option does not work due to weaknesses in the SSLeay package. A work-around in the ssl application is to set the OS environment variable SSL_CERT_FILE before SSL is started. However, then the CA certificate file will be global for all connections (both incoming and outgoing calls).

6.1.3 Configurations when Orber is Used on the Server Side

The following three configuration variables can be used to configure Orber's SSL behavior on the server side.

- `ssl_server_certfile` - which is a path to a file containing a chain of PEM encoded certificates for the Orber domain as server.
- `ssl_server_cacertfile` - which is a path to a file containing a chain of PEM encoded certificates for the Orber domain as server.
- `ssl_server_verify` - which specifies type of verification: 0 = do not verify peer; 1 = verify peer, verify client once, 2 = verify peer, verify client once, fail if no peer certificate. The default value is 0.
Chapter 6: How to use security in Orber

- \texttt{ssl\_server\_depth} - which specifies verification depth, i.e. how far in a chain of certificates the verification process shall proceed before the verification is considered successful. The default value is 1.
- \texttt{ssl\_server\_keyfile} - which is a path to a file containing a PEM encoded key for the Orber domain as server.
- \texttt{ssl\_server\_password} - only used if the private keyfile is password protected.
- \texttt{ssl\_server\_ciphers} - which is string of ciphers as a colon separated list of ciphers.
- \texttt{ssl\_server\_cachetimeout} - which is the session cache timeout in seconds.

There also exist a number of API functions for accessing the values of these variables:

- \texttt{orber:ssl\_server\_certfile/0}
- \texttt{orber:ssl\_server\_cacertfile/0}
- \texttt{orber:ssl\_server\_verify/0}
- \texttt{orber:ssl\_server\_depth/0}
- \texttt{orber:ssl\_server\_keyfile/0}
- \texttt{orber:ssl\_server\_password/0}
- \texttt{orber:ssl\_server\_ciphers/0}
- \texttt{orber:ssl\_server\_cachetimeout/0}

6.1.4 Configurations when Orber is Used on the Client Side

When the Orber enabled application is the client side in the secure connection the different configurations can be set per client process instead and not for the whole domain as for incoming calls. One can use configuration variables to set default values for the domain but they can be changed per client process. Below is the list of client configuration variables.

- \texttt{ssl\_client\_certfile} - which is a path to a file containing a chain of PEM encoded certificates used in outgoing calls in the current process.
- \texttt{ssl\_client\_cacertfile} - which is a path to a file containing a chain of PEM encoded CA certificates used in outgoing calls in the current process.
- \texttt{ssl\_client\_verify} - which specifies type of verification: 0 = do not verify peer; 1 = verify peer, verify client once, 2 = verify peer, verify client once, fail if no peer certificate. The default value is 0.
- \texttt{ssl\_client\_depth} - which specifies verification depth, i.e. how far in a chain of certificates the verification process shall proceed before the verification is considered successful. The default value is 1.
- \texttt{ssl\_client\_keyfile} - which is a path to a file containing a PEM encoded key when Orber act as client side ORB.
- \texttt{ssl\_client\_password} - only used if the private keyfile is password protected.
- \texttt{ssl\_client\_ciphers} - which is string of ciphers as a colon separated list of ciphers.
- \texttt{ssl\_client\_cachetimeout} - which is the session cache timeout in seconds.

There also exist a number of API functions for accessing and changing the values of this variables in the client processes.

Access functions:

- \texttt{orber:ssl\_client\_certfile/0}
- orber:ssl_client_certfile/0
- orber:ssl_client_verify/0
- orber:ssl_client_depth/0
- orber:ssl_client_keyfile/0
- orber:ssl_client_password/0
- orber:ssl_client_ciphers/0
- orber:ssl_client_cachetimeout/0

Modify functions:
- orber:set_ssl_client_certfile/1
- orber:set_ssl_client_cacertfile/1
- orber:set_ssl_client_verify/1
- orber:set_ssl_client_depth/1
Chapter 7

Service Implementation

This chapter describes how to implement ORB-based CORBA services.

7.1 Orber Examples

7.1.1 A Tutorial on How to Create a SimpleStack

Interface Design

This example uses a very simple stack server. The specification contains two interfaces: the first is the Stack itself and the other is the StackFactory which is used to create new stacks. The specification is in the file stack.idl.

```c
#ifndef _STACK_IDL
#define _STACK_IDL

module StackModule {

exception EmptyStack {};

interface Stack {

long pop() raises(StackModule::EmptyStack);

void push(in long value);

void empty();

};

interface StackFactory {

StackModule::Stack create_stack();

void destroy_stack(in StackModule::Stack s);

};
```

Orber Application
Generating Erlang Code

Run the IDL compiler on this file by calling the `ic:gen/1` function

```erlang
1> ic:gen("stack").
```

This will produce the client stub and server skeleton. Among other files a stack API module named `StackModule.Stack.erl` will be produced. This will produce among other files a stack API module called `StackModule.Stack.erl` which contains the client stub and the server skeleton.

Implementation of Interface

After generating the API stubs and the server skeletons it is time to implement the servers and if no special options are sent to the IDL compiler the file name should be `<global interface name>_impl.erl`, in our case `StackModule.Stack_impl.erl`.

```erlang
%% StackModule_Stack_impl example file.
-module('StackModule_Stack_impl').
-includelib("orber/include/corba.hrl").
-includelib("orber/examples/Stack/StackModule.hrl").
-export([pop/1, push/2, empty/1, init/1, terminate/2]).

init(Env) ->
    {ok, []}.

terminate(From, Reason) ->
    ok.

push(Stack, Val) ->
    {reply, ok, [Val | Stack]}.  

pop([Val | Stack]) ->
    {reply, Val, Stack};

pop([]) ->
    corba:raise(#'StackModule_EmptyStack'{}).

empty(_) ->
    {reply, ok, []}.

We also have the factory interface which is used to create new stacks and that implementation is in the file `StackModule.StackFactory_impl.erl`.```
7.1: Orber Examples

%% StackModule_StackFactory_impl example file.
-module('StackModule_StackFactory_impl').
-include_lib("orber/include/corba.hrl").
-export([create_stack/1, destroy_stack/2, init/1, terminate/2]).

init(Env) ->
    {ok, []}.

terminate(From, Reason) ->
    ok.

create_stack(State) ->
    %% Just a create we don’t want a link.
    {reply, 'StackModule_Stack':oe_create(), State}.

destroy_stack(State, Stack) ->
    {reply, corba:dispose(Stack), State}.

To start the factory server one executes the function StackModule_StackFactory:oe_create/0 which in this example is done in the module stack_factory.erl where the started service is also registered in the name service.

%% stack_factory example file.
-module('stack_factory').
-include_lib("orber/include/corba.hrl").
-include_lib("orber/COSS/CosNaming/CosNaming.hrl").
-include_lib("orber/COSS/CosNaming/lname.hrl").
-export([start/0]).

start() ->
    SFok = 'StackModule_StackFactory':oe_create(),
    NS = corba:resolve_initial_references("NameService"),
    NC = lname_component:set_id(lname_component:create(), "StackFactory"),
    N = lname:insert_component(lname:create(), 1, NC),
    'CosNaming_NamingContext':bind(NS, N, SFok).

Writing a Client in Erlang

At last we will write a client to access our service.

%% stack_client example file.
-module('stack_client').
-include_lib("orber/include/corba.hrl").
-include_lib("orber/COSS/CosNaming/CosNaming.hrl").
-include_lib("orber/COSS/CosNaming/lname.hrl").
-export([run/0, run/1]).
run() ->
    NS = corba:resolve_initial_references("NameService"),
    run_1(NS).
run(HostRef) ->
    NS = corba:resolve_initial_references_remote("NameService", HostRef),
    run_1(NS).
run_1(NS) ->
    NC = lname_component:set_id(lname_component:create(), "StackFactory"),
    N = lname:insert_component(lname:create(), 1, NC),
    case catch 'CosNaming_NamingContext':resolve(NS, N) of
        { 'EXCEPTION', E } ->
            io:format("The stack factory server is not registered~n",[]);
        SF ->
            %% Create the stack
            SS = 'StackModule_StackFactory':create_stack(SF),
            %% io:format("SS pid ~w~n", [iop_ior:get_key(SS)]),
            'StackModule_Stack':push(SS, 4),
            'StackModule_Stack':push(SS, 7),
            'StackModule_Stack':push(SS, 1),
            'StackModule_Stack':push(SS, 1),
            Res = 'StackModule_Stack':pop(SS),
            io:format("~w~n", [Res]),
            Res1 = 'StackModule_Stack':pop(SS),
            io:format("~w~n", [Res1]),
            Res2 = 'StackModule_Stack':pop(SS),
            io:format("~w~n", [Res2]),
            Res3 = 'StackModule_Stack':pop(SS),
            io:format("~w~n", [Res3]),
            %% Remove the stack
            'StackModule_StackFactory':destroy_stack(SF, SS)
    end.

Writing a Client in Java

To write a Java client for Orber you must have another ORB that uses IIOP for client-server communication and supports a Java language mapping. It must also have support for IDL:CosNaming/NamingContext or IDL:CosNaming/NamingContextExt. If the client ORB supports Interoperable Naming Service the Java Client can look like:

/*
 * Stack example using Interoperable Naming Service.
 */
package StackModule;
import org.omg.CORBA.*;
import org.omg.CORBA.SystemException;
import org.omg.CORBA.ORB.*;

public class StackClient
{
    public static void main(String args[])
    {
        org.omg.CORBA.Object objRef;
        StackFactory sfRef = null;
        Stack sRef = null;
        // The argument can look like
        // "corbaname::host:4001/#StackFactory"
        String corbaName = new String(args[0]);
        try{
            ORB orb = ORB.init(args, null);

            objRef = orb.string_to_object(corbaName);
            sfRef = StackFactoryHelper.narrow(objRef);
            sRef = sfRef.create_stack();

            sRef.push(4);
            sRef.push(7);
            sRef.push(1);
            sRef.push(1);

            try{
                System.out.println(sRef.pop());
                System.out.println(sRef.pop());
                System.out.println(sRef.pop());
                System.out.println(sRef.pop());
                // The following operation shall
                // return an EmptyStack exception
                System.out.println(sRef.pop());
            }
            catch(EmptyStack es) {
                System.out.println("Empty stack");
            }
            sfRef.destroy_stack(sRef);
        }
        catch(SystemException se)
        {
            System.out.println("Unexpected exception: " + se.toString());
            return;
        }
    }
}

If the Client ORB does not support Interoperable Naming Service, a Java package named Orber is included with our product. It contains just one class, InitialReference which can be used to get the initial reference to Orber’s naming service. The Java client will then look like this:

Orber Application
Chapter 7: Service Implementation

/*@ Stack example.*/

package StackModule;
import org.omg.CosNaming.*;
import org.omg.CORBA.*;
import org.omg.CORBA.SystemException;
import org.omg.CORBA.ORB.*;

public class StackClient
{
    public static void main(String args[])
    {
        try
        {
            ORB orb = ORB.init(args, null);
            // Create Initial reference (objectkey "INIT").
            String s = ir.stringified_ior(srvHost, srvPort.intValue());
            initRef = orb.string_to_object(s);
            init = Orber.InitialReferencesHelper.narrow(initRef);
            // Fetch name service reference.
            nsRef = init.get("NameService");
            nsContext = NamingContextHelper.narrow(nsRef);
            // Create a name
            name[0] = new NameComponent("StackFactory", ";");
            try
            {
                objRef = nsContext.resolve(name);
            }
            catch(Exception n)
            {
                System.out.println("Unexpected exception: " + n.toString());
                return;
            }
            sfRef = StackFactoryHelper.narrow(objRef);
            sRef = sfRef.create_stack();
        }
    }
}
sRef.push(4);
sRef.push(7);
sRef.push(1);
sRef.push(1);

try
{
    System.out.println(sRef.pop());
    System.out.println(sRef.pop());
    System.out.println(sRef.pop());
    System.out.println(sRef.pop());
    // The following operation shall return an EmptyStack exception
    System.out.println(sRef.pop());
}
catch(EmptyStack es)
{
    System.out.println("Empty stack");
};

sfRef.destroy_stack(sRef);

catch(SystemException se)
{
    System.out.println("Unexpected exception: "+ se.toString());
    return;
}
}

**Note:**
If an ORB does not support CosNaming at all the cos Naming.idl file must be compiled and imported.

**Building the Example**

To build the example for access from a Java client you need a Java enabled ORB. The build log below, using OrbixWeb's IDL compiler, describes the scenario where the Client ORB does not support Naming Service.

```
fingolfin 127> erl
Erlang (BEAM) emulator version 4.9

Eshell V4.9 (abort with ~G)
1> ic:gen(stack).
Erlang IDL compiler version 20
ok
2> make:all().
Recompile: oe_stack
```
Recompile: StackModule_StackFactory
Recompile: StackModule_Stack
Recompile: StackModule
Recompile: stack_client
Recompile: stack_factory
Recompile: StackModule_StackFactory_impl
Recompile: StackModule_Stack_impl
up_to_date
3>
BREAK: (a)bort (c)ontinue (p)roc info (i)nfo (l)oaded 
   (v)ersion (k)ill (D)b-tables (d)istribution

fingolfin 128> idl stack.idl
fingolfin 129> idl InitialReferences.idl
fingolfin 130> idl <OTP_INSTALLATIONPATH>/lib/orber-<Orber Version>/C OSS/ 
   CosNaming/cos_naming.idl
fingolfin 131>

How to Run Everything

Below is a short transcript on how to run Orber. The commands for starting the new socket 
communication package will not be necessary when it is used as default in OTP R3A. In R2 it is only 
available unsupported, and without documentation but Orber uses this for better IIOP performance.

An example .inetrc can also be found in Orber's example directory and is named inetrc (without the 
starting ).

fingolfin 143> erl
Erlang (BEAM) emulator version 4.9

Eshell V4.9   (abort with "G")
1> mnesia:create_schema([]).
ok
2> orber:install([]).
ok
3> orber:start().
ok
4> oe_stack:oe_register().
ok
Before testing the Java part of this example generate and compile Java classes for `orber/examples/stack.idl`, `orber/examples/InitialReferences.idl` and `orber/COS/CosNaming/cos_naming.idl` as seen in the build example. We have tested with OrbixWeb.

To run the Java client use the following command (the second parameter is the port number for the bootstrap port):

```
fingolfin 38> java StackModule.StackClient fingolfin 4001
[New Connection (fingolfin,4001, null,null,pid=0) ]
[New Connection (fingolfin.du.etx.ericsson.se,4001, null,null,pid=0) ]
1
1
7
4
```

Empty stack

### 7.1.2 A Tutorial on How to Start Orber as Lightweight

#### Preparation

When starting Erlang the configuration parameter `lightweight` must be used. The value is set to a list of remote modifiers, equal to the `orber:resolve_initial_references/remote/2` argument, i.e., “iiop://host:port”. On these given nodes, all necessary `oeX:oe_register()` calls must be done before running a Orber lightweight.

Lightweight Orber do not allow us to:

- Create objects locally
- Accept incoming requests
- Access local NameService
- Register data in the IFR

With lightweight Orber we do not:

- Start Mnesia
- Run `orber:install/1`

To be able to start objects we must supply a factory on a non-lightweight node(s) which can start necessary objects. One way to accomplish this is:
Chapter 7: Service Implementation

smaug 125> erl -orber domain "ORBER_MAIN"
Erlang (BEAM) emulator version 4.9

Eshell V4.9  (abort with ^G)
1> mnesia:create_schema([]).
2> orber:install([]).
3> orber:start().
4> oe_MyFactory:oe_register().
5> oe_MyObjects:oe_register(). % Do this for all objects necessary.
6> Factory=MyFactory_Creater:oe_create().
7> NS=orber:resolve_initial_references("NameService").
8> NC= lname_component:set_id(lname_component:create(), "myFactory").
9> N = lname:insert_component(lname:create(), 1, NC).
10> 'CosNaming_NamingContext':bind(NS, N, Factory)).

Now we have a factory we can access from, hence, we can now start a lightweight Orber:

fingolfin 14> erl -orber lightweight ["iiop://host1:port",
   
"iiop://host2:port"]
   
   -orber domain "ORBER_LIGHT"
Erlang (BEAM) emulator version 4.9

Eshell V4.9  (abort with ^G)
1> orber:start_lightweight().
2> Fac=corba:string_to_object("corbaname::Host:Port/NameService#myFactory"),
3> Obj=MyFactory_Creater:MyObject(Fac, Args).
4> MyObject:myFunction(Obj,Args2).

It is not necessary to start both Orber types using the configuration parameter domain, but at least one of them.

7.2 Orber Stubs/Skeletons

7.2.1 Orber Stubs and Skeletons Description

This example describes the API and behavior of Orber stubs and skeletons.

Server Start

Orber servers can be started in several ways. The chosen start functions determines how the server can be accessed and its behavior.

Using Module Interface:oe_create() or oe_create_link():

- No initial data can be passed.
- Cannot be used as a supervisor child start function.
- Only accessible through the object reference returned by the start function. The object reference is no longer valid if the server dies and is restarted.

Using Module Interface:oe_create(Env) or oe_create_link(Env):

- Initial data can be passed using Env.
7.2: Orber Stubs/Skeletons

- Cannot be used as a supervisor child start function.
- Only accessible through the object reference returned by the start function. The object reference is no longer valid if the server dies and is restarted.

**Using Module::Interface:oe_create(Env, Options):**

- Initial data can be passed using Env.
- Cannot be used as a supervisor child start function.
- Accessible through the object reference returned by the start function. If the option \{regname, RegName\} is used the object reference stays valid even if the server has been restarted.
- If the options \{persistent, true\} and \{regname, \{global, Name\}\} is used, the result from an object invocation will be the exception 'OBJECT_NOT_EXIST' only if the object has terminated with reason normal or shutdown. If the object is in the process of restarting, the result will be \{error, Reason\} or a system exception is raised.
- The option \{pseudo, true\} makes it possible to start create non-server objects. There are, however, some limitations, which are further described in the Pseudo objects section.

**Using Module::Interface:oe_create_link(Env, Options):**

- Initial data can be passed using Env.
- Can be used as a supervisor child start function if the option \{sup_child, true\} used.
- Accessible through the object reference returned by the start function. If the option \{regname, RegName\} is used the object reference stays valid even if the server has been restarted.
- If the options \{persistent, true\} and \{regname, \{global, Name\}\} is used, the result from an object invocation will be the exception 'OBJECT_NOT_EXIST' only if the object has terminated with reason normal or shutdown. If the object is in the process of restarting, the result will be \{error, Reason\} or a system exception is raised.
- For starting a server as a supervisor child you should use the options \{\{persistent, true\}, \{regname, \{global, Name\}\}, \{sup_child, true\}\} and of type transient. This configuration allows you to delegate restarts to the supervisor and still be able to use the same object reference and be able to see if the server is permanently terminated. Please note you must use supervisor/stdlib-1.7 or later and that it returns \{ok, Pid, Object\} instead of just \{Object\}.
- Using the option \{pseudo, true\} have the same effect as using oe_create/2.

**Warning:**

To avoid flooding Orber with old object references start erlang using the flag -orber objectkeys_gc_time Time, which will remove all object references related to servers being dead for Time seconds. To avoid extra overhead, i.e., performing garbage collect if no persistent objects are started, the objectkeys_gc_time default value is infinity. For more information, see the orber and corba documentation.

**Warning:**

Orber still allow oe_create(Env, \{Type,RegName\}) and oe_create_link(Env, \{Type,RegName\}) to be used, but may not in future releases.
Chapter 7: Service Implementation

Pseudo Objects

This section describes Orber pseudo objects.

The Orber stub can be used to start a pseudo object, which will create a non-server implementation.

A pseudo object introduce some limitations:

- The functions `oe_create_link/2` is equal to `oe_create/2`, i.e., no link can or will be created.
- The BIFs `self()` and `process_flag(trap_exit, true)` behaves incorrectly.
- The IC option `{{impl, "M::I"}, "other_impl"}` has no effect. The call-back functions must be implemented in a file called `M_I_impl.erl`.
- The call-back functions must be implemented as if the IC option `this, "M::I"` was used.
- The `gen_server` state changes have no effect. The user can provide information via the `Env` start parameter and the state returned from `init/2` will be the state passed in following invocations.
- The server reply `Timeout` has no effect.
- The `compile` option from has no effect.
- The option `pseudo, true` overrides all other start options.
- Only the functions, besides own definitions `init/2` (called via `oe_create/2`) and `terminate/2` (called via `corba:dispose/1`) must be implemented.

By adopting the rules for pseudo objects described above we can use `oe_create/2` to create server or pseudo objects, by excluding or including the option `pseudo, true`, without changing the call-back module.

To create a pseudo object do the following:

```
fingolfin 127> erl
Erlang (BEAM) emulator version 4.9

Eshell V4.9 (abort with ^G)
1> ic:gen(myDefinition, [{this, "MyModule::MyInterface"}]).
Erlang IDL compiler version 20
ok
2> make:all().
Recompile: oe_MyDefinition
Recompile: MyModule_MyInterface
Recompile: MyModule_MyInterface_impl
up_to_date
3> PseudoObj = MyModule_MyInterface:oe_create(Env, [{pseudo, true}]).
```

The call-back functions must be implemented as `MyFunction(OE_THIS, State, Args)`, and called by `MyModule_MyInterface:MyFunction(PseudoObj, Args)`.

Call-back Module

This section provides an example of how a call-back module may be implemented.

```
Note:
Arguments and Replies are determined by the IDL-code and, hence, not further described here.
```

Chapter 8

CORBA System and User Defined Exceptions

8.1 System Exceptions

Orber, or any other ORB, may raise system exceptions. These exceptions contain status- and minor-fields and may not appear in the operation's raises exception IDL-definition.

8.1.1 Status Field

The status field indicates if the request was completed or not and will be assigned one of the following erlang atoms:

<table>
<thead>
<tr>
<th>Status</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>'COMPLETED YES'</td>
<td>The operation was invoked on the target object but an error occurred after the object replied. This occur, for example, if a server replies but Orber is not able to marshal and send the reply to the client ORB.</td>
</tr>
<tr>
<td>'COMPLETED NO'</td>
<td>Orber failed to invoke the operation on the target object. This occur, for example, if the object no longer exists.</td>
</tr>
<tr>
<td>'COMPLETED MAYBE'</td>
<td>Orber invoked the operation on the target object but an error occured and it is impossible to decide if the request really reached the object or not.</td>
</tr>
</tbody>
</table>

Table 8.1: System Exceptions Status

8.1.2 Minor Field

The minor field contains an integer (VMCID), which is related to a more specific reason why an invocation failed. The function orber:exception_info/1 can be used to map the minor code to a string. Note, for VMCID:s not assigned by the OMG or Orber, the documentation for that particular ORB must be consulted.
8.1.3 Supported System Exceptions

The OMG CORBA specification defines the following exceptions:

- 'BAD_CONTEXT' - if a request does not contain a correct context this exception is raised.
- 'BAD_INVORDER' - this exception indicates that operations have been invoked in the wrong order, which would cause, for example, a dead-lock.
- 'BAD_OPERATION' - raised if the target object exists, but that the invoked operation is not supported.
- 'BAD_PARAM' - is thrown if, for example, a parameter is out of range or otherwise considered illegal.
- 'BAD_TYPECODE' - if illegal type code is passed, for example, encapsulated in an any data type the 'BAD_TYPECODE' exception will be raised.
- 'BAD_QOS' - raised whenever an object cannot support the required quality of service.
- 'CODESET_INCOMPATIBLE' - raised if two ORB's cannot communicate due to different representation of, for example, char and/or wchar.
- 'COMM_FAILURE' - raised if an ORB is unable to setup communication or it is lost while an operation is in progress.
- 'DATA_CONVERSION' - raised if an ORB cannot convert data received to the native representation. See also the 'CODESET_INCOMPATIBLE' exception.
- 'FREE_M EM' - the ORB failed to free dynamic memory and failed.
- 'IMP_LIMIT' - an implementation limit was exceeded in the ORB at run time. A object factory may, for example, limit the number of object clients are allowed to create.
- 'INTERNAL' - an internal failure occurred in an ORB, which is unrecognized. You may consider contacting the ORB provider's support.
- 'INTF_REPOS' - the ORB was not able to reach the interface repository, or some other failure relating to the interface repository is detected.
- 'INITIALIZE' - the ORB initialization failed due to, for example, network or configuration error.
- 'INVALID_TRANSACTION' - is raised if the request carried an invalid transaction context.
- 'INVALID_FLAG' - an invalid flag was passed to an operation, which caused, for example, a connection to be closed.
- 'INVALIDIDENT' - this exception indicates that an IDL identifier is incorrect.
- 'INVOKEOBJREF' - this exception is raised if an object reference is malformed or a nil reference (see also corba: create nil objref/0).
- 'INVPOLO' - the invocation cannot be made due to an incompatibility between policy overrides that apply to the particular invocation.
- 'MARSHAL' - this exception may be raised by the client- or server-side when either ORB is unable to marshal/unmarshal requests or replies.
- 'NO_JMLEMENT' - if the operation exists but no implementation exists, this exception is raised.
- 'NO_MEMORY' - the ORB has run out of memory.
- 'NO_PERMISSION' - the caller has insufficient privileges, such as, for example, bad SSL certificate.
- 'NO_RESOURCE' - a general platform resource limit exceeded.
- 'NO_RESPONSE' - no response available of a deferred synchronous request.
8.2 User Defined Exceptions

User exceptions is defined in IDL-files and is listed in operation's raises exception listing. For example, if we have the following IDL code:

```idl
module MyModule {

    exception MyException {};  
    exception MyExceptionMsg { string ExtraInfo; };

    interface MyInterface {

        void foo()
            raises(MyException);

        void bar()
            raises(MyException, MyExceptionMsg);

        void baz();
    };
}
```

8.3 Throwing Exceptions

To be able to raise MyException or MyExceptionMsg exceptions, the generated MyModule.hrl must be included, and typical usage is:
bar(State) ->
case TestingSomething of
  ok ->
    {reply, ok, State};
  {error, Reason} when list(Reason) ->
    corba:raise(#'MyModule_MyExceptionMsg'{'ExtraInfo' = Reason});
  error ->
    corba:raise(#'MyModule_MyException'{})
end.

8.4 Catching Exceptions

Depending on which operation we invoke we must be able to handle:

- foo - MyException or a system exception.
- bar - MyException, MyExceptionMsg or a system exception.
- baz - a system exception.

Catching and matching exceptions can be done in different ways:

case catch 'MyModule_MyInterface':bar(MIReference) of
  ok ->
    %% The operation raised no exception.
    ok;
  {'EXCEPTION', #'MyModule_MyExceptionMsg'{'ExtraInfo' = Reason}} ->
    %% If we want to log the Reason we must extract 'ExtraInfo'.
    error_logger:error_msg("Operation 'bar' raised: ~p~n", [Reason]),
    ... do something ...;
  {'EXCEPTION', E} when record(E, 'OBJECT_NOT_EXIST') ->
    ... do something ...;
  {'EXCEPTION', E} ->
    ... do something ...
end.
Chapter 9

Orber Interceptors

9.1 Using Interceptors

For Inter-ORB communication, e.g., via IIOP, it is possible to intercept requests and replies. To be able to use Interceptors Orber the configuration parameter interceptors must be defined.

9.1.1 Configure Orber to Use Interceptors

The configuration parameter interceptors must be defined, e.g., as command line option:

```
erl -orber interceptors "{native, ['myInterceptor']})"
```

It is possible to use more than one interceptor; simply add them to the list and they will be invoked in the same order as they appear in the list.

One can also active and deactivate an interceptor during run-time, but this will only affect currently existing connections. For more information, consult Orber's Reference Manual regarding the operations `orber:activate_audit_trail/0/1` and `orber:activate_audit_trail/0/1`.

9.1.2 Creating Interceptors

Each supplied interceptor must export the following functions:

- `new_out_connection/3/5` - one of these operations is called when a client application calls an object residing on remote ORB. If an interceptor exports both versions, arity 3 and 5, which operation that will be invoked is Orber internal.
- `new_in_connection/3/5` - one of these operations is invoked when a client side ORB tries to set up a connection to the target ORB. If an interceptor exports both versions, arity 3 and 5, which operation that will be invoked is Orber internal.
- `out_request/6` - supplies all request data on the client side ORB.
- `out_request_encoded/6` - similar to `out_request` but the request body is encode.
- `in_request_encoded/6` - after a new request arrives at the target ORB the request data is passed to the interceptor in encoded format.
- `in_request/6` - prior to invoking the operation on the target object, the interceptor `in_request` is called.
- `out_reply/6` - after the target object replied the `out_reply` operation is called with the result of the object invocation.
- `out_reply_encoded/6` - before sending a reply back to the client side ORB this operation is called with the result in encoded format.
- `in_reply_encoded/6` - after the client side ORB receives a reply this function is called with the reply in encoded format.
- `in_reply/6` - before delivering the reply to the client this operation is invoked.
- `closed_in_connection/1` - when a connection is terminated on the client side this function is called.
- `closed_out_connection/1` - if an outgoing connection is terminated this operation will be invoked.

The operations `new_out_connection`, `new_in_connection`, `closed_in_connection` and `closed_out_connection` operations are only invoked once per connection. The remaining operations are called, as shown below, for every Request/Reply to/from remote CORBA Objects.
9.2 Interceptor Example

Assume we want to create a simple access service which purpose is to:

- Only allow incoming request from ORB’s residing on a certain set of nodes.
- Restrict the objects any client may invoke operations on.
- Only allow outgoing requests to call a limited set of external ORB’s.

Figure 9.1: The Invocation Order of Interceptor Functions.
Chapter 9: Orber Interceptors

- Add a checksum to each binary request/reply body.

To restrict the access we use a protected and named ets-table holding all information. How the ets-table is initiated and maintained is implementation specific, but it contains \{Node, ObjectTable, ChecksumModule\} where Node is used as ets-key, ObjectTable is a reference to another ets-table in which we store which objects the clients are allowed to invoke operations on and ChecksumModule determines which module we should use to handle the checksums.

```
new_in_connection(Arg, Host, Port) ->
  %% Since we only use one interceptor we do not care about the
  %% input Arg since it is set do undefined by Orber.
  case ets:lookup(in_access_table, Host) of
    [] ->
      %% We may want to log the Host/Port to see if someone tried
      %% to hack in to our system.
      exit("Access not granted");
    [{Host, ObjTable, ChecksumModule}] ->
      {ObjTable, ChecksumModule}
  end.
```

The returned tuple, i.e., \{ObjTable, ChecksumModule\}, will be passed as the first argument whenever invoking one of the interceptor functions. Unless the connection attempt did not fail we are now ready for receiving requests from the client side ORB.

When a new request comes in the first interceptor function to be invoked is \texttt{in_request_encoded}. We will remove the checksum from the coded request body in the following way:

```
in_request_encoded({ObjTable, ChecksumModule}, ObjKey, Ctx, Op, Bin, Extra) ->
  NewBin = ChecksumModule:remove_checksum(Bin),
  {NewBin, Extra}.
```

If the checksum check fails the \texttt{ChecksumModule} should invoke \texttt{exit/1}. But if the check succeeded we are now ready to check if the client-ORB objects are allowed to invoke operations on the target object. Please note, it is possible to run both checks in \texttt{in_request_encoded}. Please note, the checksum calculation must be relatively fast to ensure a good throughput.

If we want to we can restrict any clients to only use a subset of operations exported by a server:

```
in_request({ObjTable, ChecksumModule}, ObjKey, Ctx, Op, Params, Extra) ->
  case ets:lookup(ObjTable, {ObjKey, Op}) of
    [] ->
      exit("Client tried to invoke illegal operation");
    [SomData] ->
      {Params, Extra}
  end.
```

At this point \texttt{Orber} are now ready to invoke the operation on the target object. Since we do not care about what the reply is the \texttt{out_reply} function do nothing, i.e.:

```
out_reply(_, _, _, _, Reply, Extra) ->
  {Reply, Extra}.
```

If the client side ORB expects a checksum to be added to the reply we add it by using:
9.2: Interceptor Example

out_reply_encoded({ObjTable, ChecksumModule}, ObjKey, Ctx, Op, Bin, Extra) ->
    NewBin = ChecksumModule:add_checksum(Bin),
    {NewBin, Extra}.

**Warning:**
If we manipulate the binary as above the behaviour must be Bin ==
remove_checksum(add_checksum(Bin)).

For outgoing requests the principle is the same. Hence, it is not further described here. The complete interceptor module would look like:

```
-module(myInterceptor).
%% Interceptor functions.
-export([new_out_connection/3,
    new_in_connection/3,
    closed_in_connection/1,
    closed_out_connection/1,
    in_request_encoded/6,
    in_reply_encoded/6,
    out_reply_encoded/6,
    out_request_encoded/6,
    in_request/6,
    in_reply/6,
    out_reply/6,
    out_request/6]).

new_in_connection(Arg, Host, Port) ->
    %% Since we only use one interceptor we do not care about the
    %% input Arg since it is set do undefined by Orber.
    case ets:lookup(in_access_table, Host) of
        [] ->
            %% We may want to log the Host/Port to see if someone tried
            %% to hack in to our system.
            exit("Access not granted");
        [{Host, ObjTable, ChecksumModule}] ->
            {ObjTable, ChecksumModule}
    end.

ew_out_connection(Arg, Host, Port) ->
    case ets:lookup(out_access_table, Host) of
        [] ->
            exit("Access not granted");
        [{Host, ObjTable, ChecksumModule}] ->
            {ObjTable, ChecksumModule}
    end.

in_request_encoded({_, ChecksumModule}, ObjKey, Ctx, Op, Bin, Extra) ->
    NewBin = ChecksumModule:remove_checksum(Bin),
    {NewBin, Extra}.
```
Chapter 9: Orber Interceptors

in_request({ObjTable, _, ObjKey, Ctx, Op, Params, Extra} ->
    case ets:lookup(ObjTable, {ObjKey, Op}) of
        [] ->
            exit("Client tried to invoke illegal operation");
        [SomeData] ->
            {Params, Extra}
    end.

out_reply(_, _, _, _, Reply, Extra) ->
    {Reply, Extra}.

out_reply_encoded(_, _, _, _, Bin, Extra) ->
    NewBin = ChecksumModule:add_checksum(Bin),
    {NewBin, Extra}.

out_request({ObjTable, _, ObjKey, Ctx, Op, Params, Extra} ->
    case ets:lookup(ObjTable, {ObjKey, Op}) of
        [] ->
            exit("Client tried to invoke illegal operation");
        [SomeData] ->
            {Params, Extra}
    end.

out_request_encoded(_, _, _, _, Bin, Extra) ->
    NewBin = ChecksumModule:add_checksum(Bin),
    {NewBin, Extra}.

in_reply_encoded(_, _, _, _, Bin, Extra) ->
    NewBin = ChecksumModule:remove_checksum(Bin),
    {NewBin, Extra}.

in_reply(_, _, _, _, Reply, Extra) ->
    {Reply, Extra}.

closed_in_connection(Arg) ->
    %% Nothing to clean up.
    Arg.

closed_out_connection(Arg) ->
    %% Nothing to clean up.
    Arg.

Note:
One can also use interceptors for debugging purposes, e.g., print which objects and operations are invoked with which arguments and the outcome of the operation. In conjunction with the configuration parameter orber_debug_level it is rather easy to find out what went wrong or just to log the traffic.
Chapter 10

Tools, Debugging and FAQ

This chapter describes the available tools and debugging facilities for Orber. Also contains a FAQ listing of the most common mistakes.

10.1 OrberWeb

10.1.1 Using OrberWeb

OrberWeb is intended to make things easier when developing and testing applications using Orber. The user is able to interact with Orber via a GUI by using a web browser. OrberWeb requires that the application WebTool is available and started on at least one node; if so OrberWeb can usually be used to access Orber nodes supporting the Interoperable Naming Service. How to start OrberWeb is described in Starting OrberWeb [page 94].

The OrberWeb GUI consists of a Menu Frame and a Data Frames.

The Menu Frame

The menu frame consists of:

- Node List - which node to access.
- Configuration - see how Orber on the current node is configured.
- Name Service - browse the NameService and add/remove a Context/Object.
- IFR Types - see which types are registered in IFR.
- Create Object - create a new object and, possibly, store it in the NameService.
Which nodes we can access is determined by what is returned when invoking `node()` or `nodes()`. If you cannot see a desired node in the list, you have to call `net_adm:ping(Node)`. But this requires that the node is started with the distribution switched on (e.g. `erl -sname myNode`); this also goes for the node OrberWeb is running on.

The Configuration Data Frame

When accessing the Configuration page OrberWeb presents a table containing the configuration settings for the target node.
It is also possible to change those configuration parameters which can be changed when Orber is already started. The Key-Value pairs is given as a list of tuples, e.g., [{orber.debuglevel, 5}, {iiop.timeout, 60}, {giop.version, [1,2]}]. If one tries to update a parameter which may not be changed an error message will be displayed.

The IFR Data Frame

All types registered in the IFR (Interface Repository) which have an associated IFR-id can be viewed via the IFR Data Frame. This gives the user an easy way to confirm that all necessary IDL-specifications have been properly registered. All available types are listed when choosing IFR Types in the menu.
Figure 10.3: Select Type.

After selecting a type all definitions of that particular type will be displayed. If no such bindings exists the table will be empty.

Since Orber adds definitions to the IFR when it is installed (e.g. CosNaming), not only types defined by the user will show up in the table. In the figure below you find the NameService exceptions listed.
The NameService main purpose is to make possible to bind object references, which can client applications can resolve and invoke operations on. Initially, the NameService is empty. The most common scenario, is that user applications create Contexts and add objects in the NameService. OrberWeb allows the user to do the very same thing.

When referencing an object or context you must use stringified NameComponents. For more information see the Interoperable Naming Service (page 47). In the following example we will use the string org/erlang/TheObjectName, where org and erlang will be contexts and TheObjectName the name the object will be bound to.

Since the NameService is empty in the beginning, the only thing we can do is creating a new context. Simply write org in the input field and press New Context. If OrberWeb was able to create the context or not, is shown in the completion message. If succesfull, just press the Go Back button. Now, a link named org should be listed in the table. In the right column the context type is displayed. Contexts are associated with ncontext and objects with noject.
To create the next level context (i.e. erlang), simply follow the link and repeat the procedure. If done correctly, a table containing the same data as the following figure should be the result if you follow the erlang link. Note, that the path is displayed in the yellow field.

If a context does not contain any sub-contexts or object bindings, it is possible to delete the context. If these requirements are met, a Delete Context button will appear. A completion status message will be displayed after deleting the context.

Now it is possible to bind an object using the complete name string. To find out how this is done using OrberWeb see Object Creation [page 92]. For now, we will just assume that an object have been created and bound as TheObjectName.
If you follow the TheObjectName link, data about the bound object will be presented. Note, depending on which type of object it is, the information given differs. It would, for example, not be possible to display a Pid for all types of objects since it might reside on a Java-ORB. In the figure below a CosNotification FilterFactory have been bound under the name org/erlang/TheObjectName.
OrberWeb also makes it possible to remove a binding and dispose the associated object. Pressing Unbind the binding will be removed but the object will still exist. But, if the Unbind & Dispose button is pressed, the binding will be removed and the object terminated.

The Object Creation Data Frame

This part makes it possible to create a new object and, if wanted, store it the NameService.
Create a New Object

<table>
<thead>
<tr>
<th><strong>Module</strong></th>
<th>Module_Interface</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Arguments</strong></td>
<td>&quot;String&quot;, {logfile, &quot;/tmp/MyLogFile&quot;}]</td>
</tr>
<tr>
<td><strong>Options</strong></td>
<td>[{rename, {global, &quot;TheObjectName&quot;}] }</td>
</tr>
<tr>
<td><strong>Name String</strong></td>
<td>org/erlang/TheObjectName</td>
</tr>
<tr>
<td><strong>Operation to use</strong></td>
<td>Bind, Rebind</td>
</tr>
</tbody>
</table>

Figure 10.9: Create a New Object.

- **Module** - simply type the name of the module of the object type you want to create. If the module begins with a capital letter, we normally must write 'Module_Interface'. But, when using OrberWeb, you shall NOT. Since we cannot create linked objects this is not an option.

- **Arguments** - the supplied arguments must be written as a single Erlang term. That is, as a list or tuple containing other Erlang terms. The arguments will be passed to the init function of the object. It is, however, not possible to use Erlang records. If OrberWeb is not able to parse the arguments, an error message will be displayed. If left empty, an empty list will be passed.

- **Options** - the options can be the ones listed under Module_Interface [page 126] in Orber's Reference manual. Hence, they are not further described here. But, as an example, in the figure above we started the object as globally registered. If no options supplied the object will be started as default.

- **Name String** - if left empty the object will not be registered in the NameService. Hence, it is important that you can access the object in another way, otherwise a zombie process is created. In the previous section we used the name string org/erlang/TheObjectName. If we choose the same name here, the listed contexts (i.e. org and erlang) must be created before we can create and bind the object to TheObjectName. If this requirement is not met, OrberWeb cannot bind the object. Hence, the object will be terminated and an error message displayed.

- **Operation to use** - which option choosed will determine the behaviour of OrberWeb. If you choose bind and a binding already exists an error message will be displayed and the newly started object terminated. But if you choose rebind any existing binding will over-written.
Chapter 10: Tools, Debugging and FAQ

10.1.2 Starting OrberWeb

You may choose to start OrberWeb on node, on which Orber is running or not. But the Erlang
distribution must be started (e.g. by using -sname aNodeName). Now, all you have to do is to invoke:

```
erl> webtool:start().
WebTool is available at http://localhost:8888/
Or http://127.0.0.1:8888/
```

Type one of the URL:s in your web-browser. If you want to access the WebTool application from
different machine, just replace localhost with its name. For more information, see the WebTool
documentation.

10.2 Debugging

10.2.1 Tools and FAQ

Persons who use Orber for the first time may find it hard to tell what goes wrong when trying to setup
communication between an Orber-ORB and ORB:s supplied by another vendor or another Orber-ORB.
The purpose of this chapter is to inform about the most common mistakes and what tools one can use
overcome these problems.

Tools

To begin with, Orber can be configured to run in debug mode. There are four ways to set this
parameter:

- `erl -orber orber_debug_level 10` - can be added to a start-script.
- `corba:orb_init([{orber_debug_level, 10}])` - this operation must be invoked before starting Orber.
- `orber:configure(orber_debug_level, 10)` - this operation can be invoked at any time.
- `OrberWeb` - via the Configuration menu one can easily change the configuration. For more
  information, see the OrberWeb chapter in this User's Guide.

When Orber runs in debug mode, printouts will be generated if anything abnormal occurs (not
necessarily an error). An error message typically looks like:

```
=ERROR REPORT==== 29-Nov-2001::14:09:55 ===
=================== Orber =================
[410] corba:common_create(orber_test_server, [{pseudo,trucre}]);
not a boolean(trucre).
=================== End REPORT ====
```

In the example above, we tried to create an object with an incorrect option (i.e. should have been
{pseudo,true}).

If you are not able to solve the problem, you should include all generated reports when contacting
support or using the erlang-questions mailing list.

It is easy to forget to, for example, set all fields in a struct, which one may not discover when developing
an application using Orber. When using a typed language, such faults would cause a compile time error.
To avoid these mistakes, Orber allows the user to activate automatic typechecking of all local
invocations of CORBA Objects. For this feature to be really useful, the user must create test suites
which cover as much as possible. For example, invoking an operation with invalid or incorrect arguments should also be tested. This option can be activated for one object or all objects via:

- `MyModule_MyInterface:create(Env, [{local_typecheck, true}])` - This approach will only activate, or deactivate, typechecking for the returned instance. Naturally, this option can also be passed to `oe_create_link/2, corba:create/4 and corba:create_link/4`.
- `erl -orber flags 2` - can be added to a start-script. All object invocations will be typechecked, unless overridden by the previous option.
- `corba:orb_init([{flags, 16#0002}])` - this operation must be invoked before starting Orber. Behaves as the previous option.

If incorrect data is passed or returned, Orber uses the `error_logger` to generate logs, which can look like:

```
=ERROR REPORT==== 10-Jul-2002::12:36:09 ===
======== Orber Typecheck Request ========
Invoked......: MyModule_MyInterface:foo/1
Typecode.....: [{tk_enum,"IDL:MyModule/enumerant:1.0",
                "enumerant",
                ["one","two"]}]
Arguments....: [three]
Result.......: {'EXCEPTION','M ARSHAL',102,'COMPLETED_NO'}
```

Note, that the arity is equivalent to the IDL-file. In the example above, an undefined enumerant was used. In most cases, it is useful to set the configuration parameter `orber_debug_level 10` as well. Due to the extra overhead, this option MAY ONLY be used during testing and development. For more information, see also configuration settings [page 14].

It is also possible to trace all communication between an Orber-ORB and, for example, a Java-ORB, communicating via IIOP. All you need to do is to activate an interceptor [page 79]. Normally, the users must implement the interceptor themselves, but for your convenience Orber includes three pre-compiled interceptors called `orber_iiop_tracer, orber_iiop_tracer_silent and orber_iiop_tracer_stealth`.

**Warning:**
Logging all traffic is expensive. Hence, only use the supplied interceptors during test and development.

The `orber_iiop_tracer` and `orber_iiop_tracer_silent` interceptors use the `error_logger` module to generate the logs. If the traffic is intense you probably want to write the reports to a log-file. This is done by, for example, invoking:

```
erl> error_logger:tty(false).
erl> error_logger:logfile({open, "/tmp/IIOPTrace"}).
```

The IIOPTrace file will contain, if you use the `orber_iiop_tracer` interceptor, reports which looks like:
The `orber_iioptracer_silent` will not log GIOP encoded data. To activate one the interceptors, you have two options:

- `erl -orber interceptors "\{native[orber_iioptracer]\}"` - can be added to a start-script.
- `corba:orbinit\{\{interceptors \{native [orber_iioptracer_silent]\}\}\}` - this operation must be invoked before starting Orber.

It is also possible to active and deactivate an interceptor during run-time, but this will only affect currently existing connections. For more information, consult Orber's Reference Manual regarding the operations `orber:activate_audit_trail/0/1` and `orber:activate_audit_trail/0/1`.

**FAQ**

Q: When my client, typically written in C++ or Java, invoke narrow on an Orber object reference it fails?
A: You must register your application in the IFR by invoking `oe_register()`. If the object was created by a COS-application, you must run install (e.g. `cosEventApp:install()`).
A: Confirm, by consulting the IDL specifications, that the received object reference really inherit from the interface you are trying to narrow it to.

Q: I am trying to register my application in the IFR but it fails. Why?
A: If one, or more, interface in your IDL-specification inherits from other interface(s), you must register them before registering your application. Note, this also apply when you inherit interfaces supported by a COS-application. Hence, they must be installed prior to registration of your application.

Q: I have a Orber client and server residing on two different Orber instances but I only get the 'OBJECT NOT EXIST' exception, even though I am sure that the object is still alive?
A: If the two Orber-ORB's are not intended to be a part of multi-node ORB, make sure that the two Orber-ORB's have different domain names set (see configuration settings [page 14]). The easiest way to confirm this is to invoke `orber:info()` on each node.

Q: When I'm trying to install and/or start Orber it fails?
A: Make sure that no other Orber-ORB is already running on the same node. If so, change the `iiop_port` configuration parameter (see configuration settings [page 14]).
Q: My Orber server is invoked via IIOP but Orber cannot marshal the reply?
A: Consult your IDL file to confirm that your replies are of the correct type. If it is correct and the return type is, for example, a struct, make sure you have set every field in the struct. If you do not do that it will be set to the atom 'undefined', which most certainly is not correct.

A: Check that you handle inout and out parameters correctly (see the IDL specification). For example, a function which have one out-parameter and should return void, then your call-back module should return {reply, {ok, OutParam}, State}. Note, even though the return value is void (IDL) you must reply with ok.

Q: I cannot run Orber as a multi-node ORB?
A: Make sure that the Erlang distribution have been started for each node and the cookies are correct. For more information, consult the System Documentation.
Orber Reference Manual

Short Summaries

- Erlang Module **CosNaming** [page 115] – The CosNaming service is a collection of interfaces that together define the naming service.
- Erlang Module **CosNaming_BindingIterator** [page 118] – This interface supports iteration over a name binding list.
- Erlang Module **CosNaming_NamingContext** [page 120] – This interface supports different bind and access functions for names in a context.
- Erlang Module **CosNaming_NamingContextExt** [page 124] – This interface contains operation for converting a Name sequence to a string and back.
- Erlang Module **Module_Interface** [page 126] – Orber generated stubs/skeletons.
- Erlang Module **any** [page 132] – the corba any type
- Erlang Module **corba** [page 134] – The functions on CORBA module level
- Erlang Module **corba_object** [page 141] – The CORBA Object interface functions
- Erlang Module **fixed** [page 144] – the corba fixed type
- Erlang Module **interceptors** [page 146] – Describe the functions which must be exported by any supplied Orber native interceptor.
- Erlang Module **iname** [page 151] – Interface that supports the name pseudo-objects
- Erlang Module **iname_component** [page 153] – Interface that supports the name pseudo-objects
- Erlang Module **orber** [page 155] – The main module of the Orber application
- Erlang Module **orber_acl** [page 165] – Orber ACL operations
- Erlang Module **orber_diagnostics** [page 167] – Diagnostics API for Orber
- Erlang Module **orber_ifr** [page 168] – The Interface Repository stores representations of IDL information
- Erlang Module **orber_tc** [page 183] – Help functions for IDL typecodes

**CosNaming**

No functions are exported.
CosNaming_BindingIterator

The following functions are exported:

- `next_one(BindingIterator)` - Return
  [page 118] Return a binding
- `next_n(BindingIterator, HowMany)` - Return
  [page 118] Return a binding list
- `destroy(BindingIterator)` - Return
  [page 118] Destroy the iterator object

CosNaming_NamingContext

The following functions are exported:

- `bind(NamingContext, Name, Object)` - Return
  [page 121] Bind a Name to an Object
- `rebind(NamingContext, Name, Object)` - Return
  [page 121] Bind an Object to the Name even if the Name already is bound
- `bind_context(NamingContext1, Name, NamingContext2)` - Return
  [page 121] Bind a Name to an NamingContext
- `rebind_context(NamingContext1, Name, NamingContext2)` - Return
  [page 121] Bind an NamingContext to the Name even if the Name already is bound
- `resolve(NamingContext, Name)` - Return
  [page 121] Retrieve an Object bound to Name
- `unbind(NamingContext, Name)` - Return
  [page 122] Remove the binding for a Name
- `new_context(NamingContext)` - Return
  [page 122] Create a new NamingContext
- `bind_new_context(NamingContext, Name)` - Return
  [page 122] Create a new NamingContext and bind it to a Name
- `destroy(NamingContext)` - Return
  [page 122] Destroy a NamingContext
- `list(NamingContext, HowMany)` - Return
  [page 122] List returns all bindings in the context

CosNaming_NamingContextExt

The following functions are exported:

- `to_string(NamingContext, Name)` - Return
  [page 124] Stringify a Name sequence to a string
- `to_name(NamingContext, NameString)` - Return
  [page 124] Convert a stringified Name to a Name sequence
- `to_url(NamingContext, AddressString, NameString)` - Return
  [page 124] Return an URL string constructed from the given Address and Name strings
- `resolve_str(NamingContext, NameString)` - Return
  [page 124] Return the object associated, if any, with the given name string
Module Interface

The following functions are exported:

- `Module Interface::typeID() -> TypeId`
  [page 127] Return the Type ID related to this stub/skeleton
- `Module Interface::oe_create() -> ObjRef`
  [page 127] Start a Orber server.
- `Module Interface::oe_create_link() -> ObjRef`
  [page 127] Start a linked Orber server.
- `Module Interface::oe_create(Env) -> ObjRef`
  [page 127] Start a Orber server.
- `Module Interface::oe_create_link(Env) -> ObjRef`
  [page 127] Start a linked Orber server.
- `Module Interface::oe_create(Env, Options) -> ObjRef`
  [page 127] Start a Orber stub/skeleton
- `Module Interface::oe_create_link(Env, Options) -> Return`
  [page 128] Start a Orber stub/skeleton
- `Module Interface::own_functions(ObjRef, Arg1, ..., ArgN) -> Reply`
  [page 129] User defined function which is not a part of Orber
- `Module Interface::own_functions(ObjRef, Options, Arg1, ..., ArgN) -> Reply`
  [page 129] User defined function which is not a part of Orber
- `Module Interface::impl:init(Env) -> CallReply`
  [page 129] User defined function which is not a part of Orber
- `Module Interface::impl:terminate(Reason, State) -> ok`
  [page 130] User defined function which is not a part of Orber
- `Module Interface::impl:code_change(OldVsn, State, Extra) -> CallReply`
  [page 130] User defined function which is not a part of Orber
- `Module Interface::impl:handle_info(Info, State) -> CallReply`
  [page 130] User defined function which is not a part of Orber
- `Module Interface::impl:own_functions(State, Arg1, ..., ArgN) -> CallReply`
  [page 130] User defined function which is not a part of Orber
- `Module Interface::impl:own_functions(This, State, Arg1, ..., ArgN) -> CallReply`
  [page 130] User defined function which is not a part of Orber
- `Module Interface::impl:own_functions(This, From, State, Arg1, ..., ArgN) -> ExtCallReply`
  [page 130] User defined function which is not a part of Orber
- `Module Interface::impl:own_functions(From, State, Arg1, ..., ArgN) -> ExtCallReply`
  [page 130] User defined function which is not a part of Orber
- `Module Interface::impl:own_functions(State, Arg1, ..., ArgN) -> CastReply`
  [page 130] User defined function which is not a part of Orber
- `Module Interface::impl:own_functions(This, State, Arg1, ..., ArgN) -> CastReply`
  [page 130] User defined function which is not a part of Orber
any

The following functions are exported:

- `create()` -> Result
  [page 132] Create an any record
- `create(Typecode, Value)` -> Result
  [page 132] Create an any record
- `set_typecode(A, Typecode)` -> Result
  [page 132] Set the typecode field
- `get_typecode(A)` -> Result
  [page 132] Fetch the typecode
- `set_value(A, Value)` -> Result
  [page 133] Set the value field
- `get_value(A)` -> Result
  [page 133] Fetch the value

corba

The following functions are exported:

- `create(Module, TypeID)` -> Object
  [page 134] Create and start a new server object
- `create(Module, TypeID, Env)` -> Object
  [page 134] Create and start a new server object
- `create(Module, TypeID, Env, Options1)` -> Object
  [page 134] Create and start a new server object
- `create_link(Module, TypeID)` -> Object
  [page 134] Create and start a new server object
- `create_link(Module, TypeID, Env)` -> Object
  [page 134] Create and start a new server object
- `create_link(Module, TypeID, Env, Options2)` -> Reply
  [page 134] Create and start a new server object
- `dispose(Object)` -> ok
  [page 135] Stop a server object
- `create_nil_objref()` -> Object
  [page 135] Stop a server object
- `create_subobject_key(Object, Key)` -> Result
  [page 135] Add an Erlang term to a private key field
- `get_subobject_key(Object)` -> Result
  [page 136] Fetch the contents of the private key field
- `get_pid(Object)` -> Result
  [page 136] Get the process id from an object key
- `raise(Exception)`
  [page 136] Generate an Erlang throw
- `reply(To, Reply)` -> true
  [page 136] Send explicit reply to client
- `resolve_initial_references(ObjectId) -> Object`
  [page 136] Return the object reference for the given object id

- `resolve_initial_references(ObjectId, Contexts) -> Object`
  [page 136] Return the object reference for the given object id

- `add_initial_service(ObjectId, Object) -> boolean()`
  [page 137] Add a new initial service and associate it with the given id

- `remove_initial_service(ObjectId) -> boolean()`
  [page 137] Remove association between the given id and service

- `list_initial_services() -> [ObjectId]`
  [page 137] Return a list of supported object id's

- `resolve_initial_references_remote(ObjectId, Address) -> Object`
  [page 137] Return the object reference for the given object id

- `resolve_initial_references_remote(ObjectId, Address, Contexts) -> Object`
  [page 137] Return the object reference for the given object id

- `list_initial_services_remote(Address) -> [ObjectId]`
  [page 138] Return a list of supported object id's

- `list_initial_services_remote(Address, Contexts) -> [ObjectId]`
  [page 138] Return a list of supported object id's

- `object_to_string(Object) -> IOR_string`
  [page 138] Convert the object reference to the external string representation

- `string_to_object(IOR_string) -> Object`
  [page 138] Convert the external string representation to an object reference

- `string_to_object(IOR_string, Contexts) -> Object`
  [page 138] Convert the external string representation to an object reference

- `print_object(Data […, Type]) -> ok | {'EXCEPTION', E} | {'EXIT', R} | string()`
  [page 139] Print the supplied object

- `add_alternate_iiop_address(Object, Host, Port) -> NewObject | {'EXCEPTION', E}`
  [page 139] Add ALTERNATE_IIOP_ADDRESS component to the supplied local object

- `orb_init(KeyValueList) -> ok | {'EXIT', Reason}`
  [page 140] Configure Orber before starting it

**corba_object**

The following functions are exported:

- `get_interface(Object) -> InterfaceDef`
  [page 141] Fetch the interface description

- `is_nil(Object) -> boolean()`
  [page 141] Return true, if the given object is a NIL object reference, otherwise false

- `is_a(Object, Logical_type_id) -> Return`
  [page 141] Return true if the target object is an, or inherit from, object of the given type
• is_a(Object, Logical_type_id, Contexts) -> Return
  [page 141] Return true if the target object is an, or inherit from, object of the
given type
• is_remote(Object) -> boolean()
  [page 142] Determine whether or not an object reference is remote
• non_existent(Object) -> Return
  [page 142] Return false if the target object do not exist, otherwise true
• non_existent(Object, Contexts) -> Return
  [page 142] Return false if the target object do not exist, otherwise true
• not_existent(Object) -> Return
  [page 142] Return false if the target object do not exist, otherwise true
• not_existent(Object, Contexts) -> Return
  [page 142] Return false if the target object do not exist, otherwise true
• is_equivalent(Object, OtherObject) -> boolean()
  [page 142] Return true if the target object and the supplied object easily can be
determined to be equal, otherwise false
• hash(Object, Maximum) -> int()
  [page 143] Return a hash value based on the target object

fixed

The following functions are exported:
• create(Digits, Scale, Value) -> Result
  [page 145] Create a fixed type
• get_typecode(Fixed) -> Result
  [page 145] Create TypeCode representing the supplied fixed type
• add(Fixed1, Fixed2) -> Result
  [page 145] Add the supplied Fixed types
• subtract(Fixed1, Fixed2) -> Result
  [page 145] Subtract Fixed2 from Fixed1
• multiply(Fixed1, Fixed2) -> Result
  [page 145] Multiply Fixed1 with Fixed2
• divide(Fixed1, Fixed2) -> Result
  [page 145] Divide Fixed1 with Fixed2
• unary_minus(Fixed) -> Result
  [page 145] Negate the supplied Fixed Type

interceptors

The following functions are exported:
• new_in_connection(Ref, PeerHost, PeerPort) -> NewRef
  [page 147] Invoke when a new client ORB wants to setup a connection
• new_in_connection(Ref, PeerHost, PeerPort, SocketHost, SocketPort)
  -> NewRef
  [page 147] Invoke when a new client ORB wants to setup a connection
new_out_connection(Ref, PeerHost, PeerPort) -> NewRef
[page 147] Invoke when setting up a new connection to a server side ORB
new_out_connection(Ref, PeerHost, PeerPort, SocketHost, SocketPort)
-> NewRef
[page 147] Invoke when setting up a new connection to a server side ORB
closed_in_connection(Ref) -> NewRef
[page 147] Invoke when an existing connection to a client side ORB have been
terminated
closed_out_connection(Ref) -> NewRef
[page 147] Invoke when an existing connection to a server side ORB have been
terminated
in_reply(Ref, Obj, Ctx, Op, Data, Extra) -> Reply
[page 148] Invoke when replies arrives at the client side ORB
in_reply_encoded(Ref, Obj, Ctx, Op, Bin, Extra) -> Reply
[page 148] Invoke when replies arrives at the client side ORB with undecoded
reply body
in_request(Ref, Obj, Ctx, Op, Args, Extra) -> Reply
[page 148] Invoke when requests arrive at the server side ORB
in_request_encoded(Ref, Obj, Ctx, Op, Bin, Extra) -> Reply
[page 148] Invoke when requests arrive at the server side ORB with undecoded
request body
out_reply(Ref, Obj, Ctx, Op, Data, Extra) -> Reply
[page 149] Invoke after the target object replied
out_reply_encoded(Ref, Obj, Ctx, Op, Bin, Extra) -> Reply
[page 149] Invoke after the target object replied with the reply encoded
out_request(Ref, Obj, Ctx, Op, Args, Extra) -> Reply
[page 149] Invoke on the client side ORB before encoding and sending the request
out_request_encoded(Ref, Obj, Ctx, Op, Bin, Extra) -> Reply
[page 149] Invoke on the client side ORB before sending the request

Iname

The following functions are exported:
create() -> Return
[page 151] Create a new name
insert_component(Name, N, NameComponent) -> Return
[page 151] Insert a new name component in a name
get_component(Name, N) -> Return
[page 151] Get a name component from a name
delete_component(Name, N) -> Return
[page 152] Delete a name component from a name
num_components(Name) -> Return
[page 152] Count the number of name components in a name
equal(Name1, Name2) -> Return
[page 152] Test if two names are equal
less_than(Name1, Name2) -> Return
[page 152] Test if one name is lesser than the other
to_idl_form(Name) -> Return
[page 152] Transform a pseudo name to an IDL name

from_idl_form(Name) -> Return
[page 152] Transform an IDL name to a pseudo name

**name_component**

The following functions are exported:

- create() -> Return
  [page 153] Create a new name component
- get_id(NameComponent) -> Return
  [page 153] Get the id field of a name component
- set_id(NameComponent, Id) -> Return
  [page 153] Set the id field of a name component
- get_kind(NameComponent) -> Return
  [page 153] Get the kind field of a name component
- set_kind(NameComponent, Kind) -> Return
  [page 154] Set the kind field of a name component

**orber**

The following functions are exported:

- start() -> ok
  [page 155] Start the Orber application
- start(Type) -> ok
  [page 155] Start the Orber application
- start_lightweight() -> ok
  [page 155] Start the Orber application as lightweight
- start_lightweight(Addresses) -> ok
  [page 155] Start the Orber application as lightweight
- jump_start(Port) -> ok | {'EXIT', Reason}
  [page 156] Start the Orber application during tests
- stop() -> ok
  [page 156] Stop the Orber application
- info() -> ok
  [page 156] Generate Info Report, which contain Orber’s configuration settings
- info(IoType) -> ok | {'EXIT', Reason} | string()
  [page 156] Generate Info Report, which contain Orber’s configuration settings
- exception_info(Exception) -> {ok, string()} | {error, Reason}
  [page 156] Return a printable string, which describes the supplied exception
- is_lightweight() -> boolean()
  [page 156] Is the application started as lightweight?
- get_lightweight_nodes() -> RemoteModifierList | false
  [page 156] Get the Remote Modifier list.
- get_tables() -> [Tables]
  [page 156] Get the Mnesia tables Orber uses.
- `getORBInitRef()` -> string() | undefined
  [page 156] Get the initial reference address.

- `getORBDefaultInitRef()` -> string() | undefined
  [page 157] Get the initial reference address.

- `domain()` -> string()
  [page 157] Display the Orber domain name.

- `iiop_port()` -> int()
  [page 157] Display the IIOP port number.

- `iiop_out_ports()` -> 0 | {Min, Max}
  [page 157] Display the ports Orber may use when connecting to another ORB.

- `iiop_ssl_port()` -> int()
  [page 157] Display the IIOP port number used for secure connections.

- `iiop_timeout()` -> int() (milliseconds)
  [page 157] Display the IIOP timeout value.

- `iiop_connection_timeout()` -> int() (milliseconds)
  [page 157] Display the IIOP connection timeout value.

- `iiop_connections()` -> Result
  [page 158] List all existing connections to/from other ORB’s.

- `iiop_connections(Direction)` -> Result
  [page 158] List all existing connections to/from other ORB’s.

- `iiop_connections_pending()` -> Result
  [page 158] List all connections to another ORB currently being set up.

- `iiop_in_connection_timeout()` -> int() (milliseconds)
  [page 158] Display the IIOP connection timeout value for incoming connections.

- `iiop_acl()` -> Result
  [page 158] Return the ACL configuration.

- `activate_audit_trail()` -> Result
  [page 159] Activate IIOP audit/trail.

- `activate_audit_trail(Verbosity)` -> Result
  [page 159] Activate IIOP audit/trail.

- `deactivate_audit_trail()` -> Result
  [page 159] Deactivate IIOP audit/trail.

- `add_listen_interface(IP, Type)` -> Result

- `add_listen_interface(IP, Type, Port)` -> Result

- `remove_listen_interface(Ref)` -> ok

- `secure()` -> no | ssl
  [page 160] Display the security mode Orber is running in.

- `ssl_server_certfile()` -> string()
  [page 160] Display the path to the server certificate.

- `ssl_client_certfile()` -> string()
  [page 160] Display the path to the client certificate.

- `set_ssl_client_certfile(Path)` -> ok
  [page 160] Set the value of the client certificate.
ssl\server\verify() \rightarrow 0 \mid 1 \mid 2
[page 160] Display the SSL verification type for incoming calls

\ssl\client\verify() \rightarrow 0 \mid 1 \mid 2
[page 160] Display the SSL verification type for outgoing calls

set\ssl\client\verify(Value) \rightarrow ok
[page 161] Set the value of the SSL verification type for outgoing calls

ssl\server\depth() \rightarrow int()
[page 161] Display the SSL verification depth for incoming calls

ssl\client\depth() \rightarrow int()
[page 161] Display the SSL verification depth for outgoing calls

set\ssl\client\depth(Depth) \rightarrow ok
[page 161] Sets the value of the SSL verification depth for outgoing calls

objectkeys\gc\time() \rightarrow int() (seconds)
[page 161] Display the Object Keys GC time value

orber\nodes() \rightarrow RetVal
[page 161] Displays which nodes that this orber domain consist of.

install(NodeList) \rightarrow ok
[page 161] Install the Orber application

install(NodeList, Options) \rightarrow ok
[page 161] Install the Orber application

uninstall() \rightarrow ok
[page 162] Uninstall the Orber application

add\node(Node, Options) \rightarrow RetVal
[page 162] Add a new node to a group of Orber nodes

remove\node(Node) \rightarrow RetVal
[page 163] Removes a node from a group of Orber nodes

configure(Key, Value) \rightarrow ok \mid \{'EXIT', Reason\}
[page 163] Change Orber configuration.

orber\acl

The following functions are exported:

match(IP, Direction) \rightarrow boolean()
[page 165] Verify if the IP address versus the current configuration

match(IP, Direction, GetInfo) \rightarrow Reply
[page 165] Verify if the IP address versus the current configuration

verify(IP, Filter, Family) \rightarrow Reply
[page 165] Verify if the IP address versus the Filter

range(Filter, Family) \rightarrow Reply
[page 166] Get range of Filter
**Orber diagnostics**

The following functions are exported:

- `nameservice()` -> `Result`
  
  Display all objects stored in the Name Service

- `nameservice(Flags)` -> `Result`
  
  Display all objects stored in the Name Service

- `missing_modules()` -> `Count`
  
  Echo missing modules required by Orber

**Orber ifr**

The following functions are exported:

- `init(Nodes, Timeout)` -> `ok`
  
  Initialize the IFR

- `find_repository()` -> `#IFR_Repository_objref`
  
  Find the IFR object reference for the Repository

- `get_def_kind(Objref)` -> `Return`
  
  Return the definition kind of the IFR object

- `destroy(Objref)` -> `Return`
  
  Destroy, except IRO object, Contained and Container, target object and its contents

- `get_id(Objref)` -> `Return`
  
  Return the target object's repository id

- `set_id(Objref, Id)` -> `ok`
  
  Set the target object's repository id

- `get_name(Objref)` -> `Return`
  
  Return the name of the target object

- `set_name(Objref, Name)` -> `ok`
  
  Set given name to target object

- `get_version(Objref)` -> `Return`
  
  Return the version of the target object

- `set_version(Objref, Version)` -> `ok`
  
  Set given version of the target object

- `get_defined_in(Objref)` -> `Return`
  
  Return the Container the target object is contained in

- `get_absolute_name(Objref)` -> `Return`
  
  Return the absolute name of the target object

- `get_containing_repository(Objref)` -> `Return`
  
  Get the most derived Contained object associated with the target object

- `describe(Objref)` -> `Return`
  
  Return a tuple which describe the target object

- `move(Objref, New_container, New_name, New_version)` -> `Return`
  
  Move the target object from its current location to given Container, name and version
- `lookup(Objref, Search_name)` -> Return the IFR object identified by the given name
  [page 171]
- `contents(Objref, Limit_type, Exclude_inherited)` -> Return the content of the target object limited by the given constraints
  [page 171]
- `lookup_name(Objref, Search_name, Levels_to_search, Limit_type, Exclude_inherited)` -> Return a list of IFR objects matching the given name
  [page 171]
- `describe_contents(Objref, Limit_type, Exclude_inherited, Max_returnedobjs)` -> Return a list of descriptions of the IFR objects contained by the target Container object
  [page 172]
- `create_module(Objref, Id, Name, Version)` -> Return an IFR object of given type
  [page 172]
- `create_constant(Objref, Id, Name, Version, Type, Value)` -> Return a ConstantDef IFR object
  [page 172]
- `create_struct(Objref, Id, Name, Version, Members)` -> Return a StructDef IFR object
  [page 172]
- `create_union(Objref, Id, Name, Version, Discriminator_type, Members)` -> Return a UnionDef IFR object
  [page 173]
- `create_enum(Objref, Id, Name, Version, Members)` -> Return an EnumDef IFR object
  [page 173]
- `create_alias(Objref, Id, Name, Version, Original_type)` -> Return an AliasDef IFR object
  [page 173]
- `create_interface(Objref, Id, Name, Version, Base_interfaces)` -> Return an InterfaceDef IFR object
  [page 173]
- `create_exception(Objref, Id, Name, Version, Members)` -> Return an ExceptionDef IFR object
  [page 174]
- `get_type(Objref)` -> Return the typecode of the target object
  [page 174]
- `lookup_id(Objref, Search_id)` -> Return the IFR object matching the given id
  [page 174]
- `get_primitive(Objref, Kind)` -> Return a PrimitiveDef of the specified kind
  [page 174]
- `create_string(Objref, Bound)` -> Return an IFR objref of the type StringDef
  [page 174]
- `create_wstring(Objref, Bound)` -> Return an IFR objref of the type WstringDef
  [page 175]
- `create_fixed(Objref, Digits, Scale)` -> Return an IFR objref of the type FixedDef
  [page 175]
- `create_sequence(Objref, Bound, Element_type)` -> Return an IFR objref of the type SequenceDef
  [page 175]
- `create_array(Objref, Length, Element_type)` -> Return an IFR objref of the type ArrayDef
  [page 175]
- `create_idltype(Objref, Typecode)` -> Return an IFR objref of the type IDLType
  [page 175]
• get_type_def(Objref) -> Return
  [page 175] Return an IFR object of the type IDLType describing the type of the
target object
• set_type_def(Objref,TypeDef) -> Return
  [page 176] Set given TypeDef of the target object
• get_value(Objref) -> Return
  [page 176] Return the value attribute of the target ConstantDef object
• set_value(Objref,Value) -> Return
  [page 176] Set the value attribute of the target ConstantDef object
• get_members(Objref) -> Return
  [page 176] Return the members of the target object
• set_members(Objref,Members) -> Return
  [page 176] Set the members attribute of the target object
• get_discriminator_type(Objref) -> Return
  [page 177] Get the discriminator typecode of the target object
• get_discriminator_type_def(Objref) -> Return
  [page 177] Return IDLType object describing the discriminator type of the target
object
• set_discriminator_type_def(Objref,TypeDef) -> Return
  [page 177] Set the attribute discriminator_type_def for the target object to the
given TypeDef
• get_original_type_def(Objref) -> Return
  [page 177] Return an IFR object of the type IDLType describing the original type
• set_original_type_def(Objref,TypeDef) -> Return
  [page 177] Set the original_type_def attribute which describes the original type
• get_kind(Objref) -> Return
  [page 177] Return an atom describing the primitive type
• get_bound(Objref) -> Return
  [page 178] Get the maximum size of the target object
• set_bound(Objref,Bound) -> Return
  [page 178] Set the maximum size of the target object
• get_element_type(Objref) -> Return
  [page 178] Return the typecode of the elements in the IFR object
• get_element_type_def(Objref) -> Return
  [page 178] Return an IFR object of the type IDLType describing the type of the
elements in Objref
• set_element_type_def(Objref,TypeDef) -> Return
  [page 178] Set the element_type_def attribute of the target object to the given
TypeDef
• get_length(Objref) -> Return
  [page 178] Return the number of elements in the array
• set_length(Objref,Length) -> Return
  [page 179] Set the number of elements in the array
• get_mode(Objref) -> Return
  [page 179] Get the mode of the target object (AttributeDef or OperationDef)
• set_mode(Objref,Mode) -> Return
  [page 179] Set the mode of the target object (AttributeDef or OperationDef) to
the given mode
• \texttt{get\_result(Objref)} \rightarrow \texttt{Return}
  
  [page 179] Return typecode describing the type of the value returned by the operation

• \texttt{get\_result\_def(Objref)} \rightarrow \texttt{Return}
  
  [page 179] Return an IFR object of the type IDLType describing the type of the result

• \texttt{set\_result\_def(Objref,ResultDef)} \rightarrow \texttt{Return}
  
  [page 179] Set the type\_def attribute of the target object to the given ResultDef

• \texttt{get\_params(Objref)} \rightarrow \texttt{Return}
  
  [page 180] Return a list of parameter description records describing the parameters of the target OperationDef

• \texttt{set\_params(Objref,Params)} \rightarrow \texttt{Return}
  
  [page 180] Set the params attribute of the target object to the given parameter description records

• \texttt{get\_contexts(Objref)} \rightarrow \texttt{Return}
  
  [page 180] Return a list of context identifiers for the operation

• \texttt{set\_contexts(Objref,Contexts)} \rightarrow \texttt{Return}
  
  [page 180] Set the context attribute for the operation

• \texttt{get\_exceptions(Objref)} \rightarrow \texttt{Return}
  
  [page 180] Return a list of exception types that can be raised by the target object

• \texttt{set\_exceptions(Objref,Exceptions)} \rightarrow \texttt{Return}
  
  [page 180] Set the exceptions attribute for the target object

• \texttt{get\_base\_interfaces(Objref)} \rightarrow \texttt{Return}
  
  [page 181] Return a list of InterfaceDefs from which the target InterfaceDef object inherit

• \texttt{set\_base\_interfaces(Objref,BaseInterfaces)} \rightarrow \texttt{Return}
  
  [page 181] Set the BaseInterfaces attribute

• \texttt{is\_a(Objref,Interface\_id)} \rightarrow \texttt{Return}
  
  [page 181] Return a boolean if the target InterfaceDef match or inherit from the given id

• \texttt{describe\_interface(Objref)} \rightarrow \texttt{Return}
  
  [page 181] Return a full interface description record describing the InterfaceDef

• \texttt{create\_attribute(Objref,Id,Name,Version,Type,Mode)} \rightarrow \texttt{Return}
  
  [page 181] Create an IFR object of the type AttributeDef contained in the target InterfaceDef object

• \texttt{create\_operation(Objref,Id,Name,Version,Result,Mode,Params,Exceptions,Contexts)} \rightarrow \texttt{Return}
  
  [page 181] Create an IFR object of the type OperationDef contained in the target OperationDef object

\texttt{orber\_tc}

The following functions are exported:

• \texttt{null()} \rightarrow \texttt{TC}
  
  [page 183] Return the IDL typecode

• \texttt{void()} \rightarrow \texttt{TC}
  
  [page 183] Return the IDL typecode
• short() -> TC  
  [page 183] Return the IDL typecode
• unsigned_short() -> TC  
  [page 183] Return the IDL typecode
• long() -> TC  
  [page 183] Return the IDL typecode
• unsigned_long() -> TC  
  [page 183] Return the IDL typecode
• long_long() -> TC  
  [page 183] Return the IDL typecode
• unsigned_long_long() -> TC  
  [page 183] Return the IDL typecode
• wchar() -> TC  
  [page 183] Return the IDL typecode
• float() -> TC  
  [page 183] Return the IDL typecode
• double() -> TC  
  [page 183] Return the IDL typecode
• boolean() -> TC  
  [page 183] Return the IDL typecode
• char() -> TC  
  [page 183] Return the IDL typecode
• octet() -> TC  
  [page 183] Return the IDL typecode
• any() -> TC  
  [page 183] Return the IDL typecode
• typecode() -> TC  
  [page 183] Return the IDL typecode
• principal() -> TC  
  [page 183] Return the IDL typecode
• object_reference(Id, Name) -> TC  
  [page 183] Return the object_reference IDL typecode
• struct(Id, Name, ElementList) -> TC  
  [page 183] Return the struct IDL typecode
• union(Id, Name, DiscrTC, Default, ElementList) -> TC  
  [page 184] Return the union IDL typecode
• enum(Id, Name, ElementList) -> TC  
  [page 184] Return the enum IDL typecode
• string(Length) -> TC  
  [page 184] Return the string IDL typecode
• wstring(Length) -> TC  
  [page 185] Return the wstring IDL typecode
• fixed(Digits, Scale) -> TC  
  [page 185] Return the fixed IDL typecode
• sequence(ElemTC, Length) -> TC  
  [page 185] Return the sequence IDL typecode
- array(ElemTC, Length) -> TC
  [page 185] Return the array IDL typecode

- alias(Id, Name, AliasTC) -> TC
  [page 185] Return the alias IDL typecode

- exception(Id, Name, ElementList) -> TC
  [page 185] Return the exception IDL typecode

- get(tc)(Object) -> TC
  [page 186] Fetch typecode

- get(tc)(Id) -> TC
  [page 186] Fetch typecode

- check(tc)(TC) -> boolean()
  [page 186] Check syntax of an IDL typecode
CosNaming

Erlang Module

The naming service provides the principal mechanism for clients to find objects in an ORB based world. The naming service provides an initial naming context that functions as the root context for all names. Given this context clients can navigate in the name space.

Types that are declared on the CosNaming level are:

typedef string Istring;
struct NameComponent {
    Istring id;
    Istring kind;
};

typedef sequence <NameComponent> Name;
enum BindingType {nobject, ncontext};
struct Binding {
    Name     binding_name;
    BindingType binding_type;
};

typedef sequence <Binding> BindingList;

To get access to the record definitions for the structs use:

-include "lib("orber/COSS/CosNaming.hrl")";

Names are not an ORB object but the can be structured in components as seen by the definition above. There are no requirements on names so the service can support many different conventions and standards.

There are two different interfaces supported in the service:

- NamingContext
- BindingIterator

IDL specification for CosNaming:

// Naming Service v1.0 described in CORBAservices:
// Common Object Services Specification, chapter 3
// OMG IDL for CosNaming Module, p 3-6

#pragma prefix "omg.org"

module CosNaming
{

typedef string Istring;
struct NameComponent {
    Istring id;
    Istring kind;
};

typedef sequence <NameComponent> Name;
enum BindingType {nobject, ncontext};

struct Binding {
    Name binding_name;
    BindingType binding_type;
};

typedef sequence <Binding> BindingList;

interface BindingIterator;
interface NamingContext;

interface NamingContext {
    enum NotFoundReason { missing_node, not_context, not_object};

    exception NotFound {
        NotFoundReason why;
        Name rest_of_name;
    };

    exception CannotProceed {
        NamingContext cxt;
        Name rest_of_name;
    };

    exception InvalidName{);
    exception AlreadyBound {);
    exception NotEmpty{);

    void bind(in Name n, in Object obj) raises(NotFound, CannotProceed, InvalidName, AlreadyBound);
    void rebind(in Name n, in Object obj) raises(NotFound, CannotProceed, InvalidName);
    void bind_context(in Name n, in NamingContext nc) raises(NotFound, CannotProceed, InvalidName, AlreadyBound);
    void rebind_context(in Name n, in NamingContext nc) raises(NotFound, CannotProceed, InvalidName);
    Object resolve (in Name n) raises(NotFound, CannotProceed, InvalidName);  // Corrected return type
    void unbind(in Name n) raises(NotFound, CannotProceed, InvalidName);
    NamingContext new_context();
    NamingContext bind_new_context(in Name n)
Orber Reference Manual

CosNaming

    raises(NotFound, AlreadyBound, CannotProceed, InvalidName);
    void destroy( )
      raises(NotEmpty);
    void list (in unsigned long how_many,
               out BindingList bl,
               out BindingIterator bi);
    };

interface BindingIterator {
  boolean next_one(out Binding b);
  boolean next_n(in unsigned long how_many,
                 out BindingList bl);
  void destroy();
};
CosNaming_BindingIterator

Erlang Module

This interface allows a client to iterate over the Bindinglist it has been initiated with. The type NameComponent used below is defined as:

\[-\text{record('CosNaming\_NameComponent', \{id, kind='\"\}"\}).}\]

id and kind are strings.
The type Binding used below is defined as:

\[-\text{record('CosNaming\_Binding', \{binding\_name, binding\_type\}).}\]

binding\_name is a Name = [NameComponent] and binding\_type is an enum which has the values nobject and ncontext.
Both these records are defined in the file CosNaming.hrl and it is included with:

\[-\text{include\_lib("orber/COSS/CosNaming/CosNaming.hrl")}.}\]

Exports

\(\text{next\_one(BindingIterator)} \rightarrow \text{Return}\)

Types:
- BindingIterator = \#objref
- Return = \{bool(), Binding\}

This operation returns the next binding and a boolean. The latter is set to true if the binding is valid otherwise false. If the boolean is false there are no more bindings to retrieve.

\(\text{next\_n(BindingIterator, HowMany)} \rightarrow \text{Return}\)

Types:
- BindingIterator = \#objref
- HowMany = int()
- BindingList = \[Binding\]
- Return = \{bool(), BindingList\}

This operation returns a binding list with at most HowMany bindings. If there are no more bindings it returns false otherwise true.

\(\text{destroy(BindingIterator)} \rightarrow \text{Return}\)

Types:
- BindingIterator = \#objref
• Return = ok

This operation destroys the binding iterator.
CosNaming_NamingContext

Erlang Module

This is the object that defines name scopes. Names must be unique within a naming context. Objects may have multiple names and may exist in multiple naming contexts. Name context may be named in other contexts and cycles are permitted.

The type NameComponent used below is defined as:

\[-record('CosNaming_NameComponent', {id, kind=""}).\]

where id and kind are strings.

The type Binding used below is defined as:

\[-record('CosNaming_Binding', {binding_name, binding_type}).\]

where binding_name is a Name and binding_type is an enum which has the values nobject and ncontext.

Both these records are defined in the file CosNaming.hrl and it is included with:

\[-include_lib("orber/COSS/CosNaming/CosNaming.hrl").\]

There are a number of exceptions that can be returned from functions in this interface.

- **NotFound** is defined as

  \[-record('CosNaming_NamingContext_NotFound', {rest_of_name, why}).\]

- **CannotProceed** is defined as

  \[-record('CosNaming_NamingContext_CannotProceed', {rest_of_name, cxt}).\]

- **InvalidName** is defined as

  \[-record('CosNaming_NamingContext_InvalidName', {}).\]

- **NotFound** is defined as

  \[-record('CosNaming_NamingContext_NotFound', {}).\]

- **AlreadyBound** is defined as

  \[-record('CosNaming_NamingContext_AlreadyBound', {}).\]

- **NotEmpty** is defined as

  \[-record('CosNaming_NamingContext_NotEmpty', {}).\]

These exceptions are defined in the file CosNaming_NamingContext.hrl and it is included with:

\[-include_lib("orber/COSS/CosNaming/CosNaming_NamingContext.hrl").\]
Exports

**bind**(NamingContext, Name, Object) -> Return

Types:
- NameContext = #objref
- Name = [NameComponent]
- Object = #objref
- Return = ok

Creates a binding of a name and an object in the naming context. Naming contexts that are bound using `bind()` do not participate in name resolution.

**rebind**(NamingContext, Name, Object) -> Return

Types:
- NameContext = #objref
- Name = [NameComponent]
- Object = #objref
- Return = ok

Creates a binding of a name and an object in the naming context even if the name is already bound. Naming contexts that are bound using `rebind()` do not participate in name resolution.

**bind_context**(NamingContext1, Name, NamingContext2) -> Return

Types:
- NamingContext1 = NamingContext2 = #objref
- Name = [NameComponent]
- Return = ok

The `bind_context` function creates a binding of a name and a naming context in the current context. Naming contexts that are bound using `bind_context()` participate in name resolution.

**rebind_context**(NamingContext1, Name, NamingContext2) -> Return

Types:
- NamingContext1 = NamingContext2 = #objref
- Name = [NameComponent]
- Return = ok

The `rebind_context` function creates a binding of a name and a naming context in the current context even if the name already is bound. Naming contexts that are bound using `rebind_context()` participate in name resolution.

**resolve**(NamingContext, Name) -> Return

Types:
- NamingContext = #objref
- Name = [NameComponent]
- Return = Object
The resolve function is the way to retrieve an object bound to a name in the naming context. The given name must match exactly the bound name. The type of the object is not returned, clients are responsible for narrowing the object to the correct type.

unbind(NamingContext, Name) -> Return
Types:
- NamingContext = #objref
- Name = [NameComponent]
- Return = ok
The unbind operation removes a name binding from the naming context.

new_context(NamingContext) -> Return
Types:
- NamingContext = #objref
- Return = #objref
The new_context operation creates a new naming context.

bind_new_context(NamingContext, Name) -> Return
Types:
- NamingContext = #objref
- Name = [NameComponent]
- Return = #objref
The new_context operation creates a new naming context and binds it to Name in the current context.

destroy(NamingContext) -> Return
Types:
- NamingContext = #objref
- Return = ok
The destroy operation disposes the NamingContext object and removes it from the name server. The context must be empty e.g. not contain any bindings to be removed.

list(NamingContext, HowMany) -> Return
Types:
- NamingContext = #objref
- HowMany = int()
- Return = {ok, BindingList, BindingIterator}
- BindingList = [Binding]
- BindingIterator = #objref
The list operation returns a BindingList with a number of bindings up to HowMany from the context. It also returns a BindingIterator which can be used to step through the list. If the total number of existing bindings are less than, or equal to, the HowMany parameter a NIL object reference is returned.

**Note:**
One must destroy the BindingIterator, unless it is a NIL object reference, by using 'BindingIterator':destroy(). Otherwise one can get dangling objects.
CosNaming_NamingContextExt

Erlang Module

To get access to the record definitions for the structures use:
-include_lib("orber/COSS/CosNaming/CosNaming.hrl").

This module also exports the functions described in:
- CosNaming_NamingContext [page 120]

Exports

to_string(NamingContext, Name) -> Return
Types:
- NameContext = #objref
- Name = [NameComponent]
- Return = string() | {'EXCEPTION', NamingContext::InvalidName()}
Stringifies a Name sequence to a string.

to_name(NamingContext, NameString) -> Return
Types:
- NameContext = #objref
- NameString = string()
- Return = [NameComponent] | {'EXCEPTION', NamingContext::InvalidName()}
Converts a stringified Name to a Name sequence.

to_url(NamingContext, AddressString, NameString) -> Return
Types:
- NameContext = #objref
- Address = NameString = string()
- Return = URLString | {'EXCEPTION', NamingContext::InvalidName()} |
  {'EXCEPTION', NamingContextExt::InvalidAddress()}
This operation takes a corbaloc string and a stringified Name sequence as input and returns a fully formed URL string.

resolve_str(NamingContext, NameString) -> Return
Types:
- NameContext = #objref
This operation takes a stringified `Name` sequence as input and returns the associated, if any, object.
Module_Interface

Erlang Module

This module contains the stub/skeleton functions generated by IC.
Starting a Orber server can be done in three ways:

- Normal - when the server dies Orber forgets all knowledge of the server.
- Supervisor child - adding the configuration parameter {sup_child, true} the oe_create_link/2 function returns {ok, Pid, ObjRef} which can be handled by the application supervisor/stdlib-1.7 or later.
- Persistent object reference - adding the configuration parameters {persistent, true} and {regname, {global, term()}} Orber will remember the object reference until the server terminates with reason normal or shutdown. Hence, if the server is started as a transient supervisor child we do not receive a 'OBJECT_NOT_EXIST' exception when it has crashed and is being restarted.

The Orber stub can be used to start a pseudo object, which will create a non-server implementation. A pseudo object introduce some limitations:

- The functions oe_create_link/2 is equal to oe_create/2, i.e., no link can or will be created.
- The BIF:s self() and process_flag(trap_exit,true) behaves incorrectly.
- The IC option {{impl, "M::I"}, "other_impl"} has no effect. The call-back functions must be implemented in a file called M_I_impl.erl
- The IC option from has no effect.
- The call-back functions must be implemented as if the IC option {this, "M::I"} was used.
- Server State changes have no effect. The user can provide information via the Env start parameter and the State returned from init/2 will be the State passed in following invocations.
- If a call-back function replies with the Timeout parameter set it have no effect.
- Operations defined as oneway are blocking until the operation replies
- The option {pseudo, true} overrides all other start options.
- Only the functions, besides own definitions, init/2 (called via oe_create*/2) and terminate/2 (called via corba:dispose/1) must be implemented.

By adopting the rules for pseudo objects described above we can use oe_create/2 to create server or pseudo objects, by excluding or including the option {pseudo, true}, without changing the call-back module.

If you start a object without {regname, RegName} it can only be accessed through the returned object key. Started with a {regname, RegName} the name is registered locally or globally.
Warning:
To avoid flooding Orber with old object references start erlang using the flag -orber objectkeys.gc_time Time, which will remove all object references related to servers being dead for Time seconds. To avoid extra overhead, i.e., performing garbage collect if no persistent objects are started, the objectkeys.gc_time default value is infinity. For more information, see the orber and corba documentation.

Exports

Module_Interface:typeID() -> TypeId

Types:
- TypeId = string(), e.g., "IDL:Module/Interface:1.0"
Returns the Type ID related to this stub/skeleton

Module_Interface:oe_create() -> ObjRef

Types:
- ObjRef = #object reference
Start a Orber server.

Module_Interface:oe_create_link() -> ObjRef

Types:
- ObjRef = #object reference
Start a linked Orber server.

Module_Interface:oe_create(Env) -> ObjRef

Types:
- Env = term()
- ObjRef = #object reference
Start a Orber server passing Env to init/1.

Module_Interface:oe_create_link(Env) -> ObjRef

Types:
- Env = term()
- ObjRef = #object reference
Start a linked Orber server passing Env to init/1.

Module_Interface:oe_create(Env, Options) -> ObjRef

Types:
- Env = term()
- ObjRef = #object reference
Options = [{sup_child, false} | {persistent, Bool} | {regname, RegName} | {pseudo, Bool} | {local_typecheck, Bool} | {survive_exit, Bool} | {create_options, [CreateO pts]}]

Bool = true | false
RegName = {global, term()} | {local, atom()}
CreateO pts = {debug, [Dbg]} | {timeout, Time}
Dbg = trace | log | statistics | {log_to_file, FileName}

Start a Orber server passing Env to init/1.
If the option {pseudo, true} is used, all other options are overridden. As default, this option is set to false.
This function cannot be used for starting a server as supervisor child. If started as persistent, the options [{persistent, true}, {regname, {global, term()}}] must be used and Orber will only forget the object reference if it terminates with reason normal or shutdown.
The option {local_typecheck, boolean()}, which overrides the Local Typechecking environment flag, turns on or off typechecking. If activated, parameters, replies and raised exceptions will be checked to ensure that the data is correct, when invoking operations on CORBA Objects within the same Orber domain. Due to the extra overhead, this option MAY ONLY be used during testing and development.

{survive_exit, boolean()} overrides the EXIT Tolerance environment flag. If activated, the server will not terminate, even though the call-back module returns EXIT.
Time specifies how long time, in milliseconds, the server is allowed to spend initializing. For more information about the Dbg options, see the sys module.

Module_Interface: oe_create_link(Env, Options) -> Return
Types:
Env = term()
Return = ObjRef | {ok, Pid, ObjRef}
ObjRef = #object reference
Options = [{sup_child, Bool} | {persistent, Bool} | {regname, RegName} | {pseudo, Bool} | {local_typecheck, Bool} | {survive_exit, Bool} | {create_options, [CreateO pts]}]
Bool = true | false
RegName = {global, term()} | {local, atom()}
CreateO pts = {debug, [Dbg]} | {timeout, Time}
Dbg = trace | log | statistics | {log_to_file, FileName}

Start a linked Orber server passing Env to init/1.
If the option {pseudo, true} is used, all other options are overridden and no link will be created. As default, this option is set to false.
This function can be used for starting a server as persistent or supervisor child. At the moment [{persistent, true}, {regname, {global, term()}}] must be used to start a server as persistent, i.e., if a server died and is in the process of being restarted a call to the server will not raise 'OBJECT_NOT_EXIST' exception. Orber will only forget
the object reference if it terminates with reason normal or shutdown, hence, the server
must be started as transient (for more information see the supervisor documentation).

The options \{local\_typecheck, boolean()\} and \{survive\_exit, boolean()\} behaves in the same way as for oe\_create/2.

Time specifies how long time, in milliseconds, the server is allowed to spend initializing.
For more information about the Dbg options, see the sys module.

```
Module\_Interface:own\_functions(ObjRef, Arg1, ..., ArgN) \rightarrow Reply
Module\_Interface:own\_functions(ObjRef, Options, Arg1, ..., ArgN) \rightarrow Reply
```

Types:
- \type{ObjRef} = #object reference
- \type{Options} = \[Option\] | \type{Timeout}
- \type{Option} = \{timeout, Timeout\} | \{context, \[Context\]\}
- \type{Timeout} = infinity | integer(milliseconds)
- \type{Context} = \#'IOP\_ServiceContext'\{context\_id = CtxId, context\_data = CtxData\}
- \type{CtxId} = ?ORBER\_GENERIC\_CTX\_ID
- \type{CtxData} = \{interface, Interface\} | \{userspecific, term()\}
- \type{Interface} = string()
- \type{ArgsX} = specified in the IDL-code.
- \type{Reply} = specified in the IDL-code.

The default value for the Timeout option is infinity. IPv4 or IPv6 addresses are accepted as local Interface.

To gain access to \#'IOP\_ServiceContext'\{\} record and the \?ORBER\_GENERIC\_CTX\_ID
macro, you must add \:-include\lib("orber/include/corba.hrl"). to your module.

**CALLBACK FUNCTIONS**

The following functions should be exported from a CORBA callback module. Note, a complete template of the call-back module can be generated automatically by compiling the IDL-file with the IC option \{be, e\_template\}. One should also add the same compile options, for example this or from, used when generating the stub/skeleton modules.

**Exports**

```
Module\_Interface\_impl:init(Env) \rightarrow CallReply
```

Types:
- \type{Env} = term()
- \type{CallReply} = \{ok, State\} | \{ok, State, Timeout\} | ignore | \{stop, StopReason\}
- \type{State} = term()
- \type{Timeout} = int() \geq 0 | infinity
- \type{StopReason} = term()
Whenever a new server is started, init/1 is the first function called in the specified call-back module.

**Module Interface impl:terminate(Reason, State) -> ok**

Types:
- Reason = term()
- State = term()
This call-back function is called whenever the server is about to terminate.

**Module Interface impl:code_change(OldVsn, State, Extra) -> CallReply**

Types:
- OldVsn = undefined | term()
- State = term()
- Extra = term()
- CallReply = {ok, NewState}
- NewState = term()
Update the internal State.

**Module Interface impl:handle_info(Info, State) -> CallReply**

Types:
- Info = term()
- State = term()
- CallReply = {noreply, State} | {noreply, State, Timeout} | {stop, StopReason, State}
- Timeout = int() > 0 | infinity
- StopReason = normal | shutdown | term()
If the configuration parameter `{handle_info, "Module:Interface"}, true` is passed to IC and process_flag(trap_exit, true) is set in the init() call-back this function must be exported.

**Note:**
To be able to handle the Timeout option in CallReply in the call-back module the configuration parameter `{handle_info, "Module:Interface"}, true` must be passed to IC.

**Module Interface impl:own_functions(State, Arg1, ..., ArgN) -> CallReply**
**Module Interface impl:own_functions(This, State, Arg1, ..., ArgN) -> CallReply**
**Module Interface impl:own_functions(This, From, State, Arg1, ..., ArgN) -> ExtCallReply**
**Module Interface impl:own_functions(From, State, Arg1, ..., ArgN) -> ExtCallReply**

Types:
- This = the servers #object reference
- State = term()
- ArgX = specified in the IDL-code.
All two-way functions must return one of the listed replies or raise any of the exceptions listed in the IDL code (i.e. raises(...)). If the IC compile options this and/or from are used, the implementation must accept the This and/or From parameters.

Types:

- This = the servers #object reference
- State = term()
- CastReply = {noreply, State} | {noreply, State, Timeout} | {stop, StopReason, State} | {stop, StopReason, State} | corba:raise(Exception)
- ArgX = specified in the IDL-code.
- Reply = specified in the IDL-code.
- Timeout = int() >= 0 | infinity
- StopReason = normal | shutdown | term()

All one-way functions must return one of the listed replies. If the IC compile option this is used, the implementation must accept the This parameter.
any

Erlang Module

This module contains functions that gives an interface to the CORBA any type. Note that the any interface in orber does not contain a destroy function because the any type is represented as an Erlang record and therefore will be removed by the garbage collector when not in use.

The type TC used below describes an IDL type and is a tuple according to the to the Erlang language mapping. The type Any used below is defined as:

```erlang
-record(any, {typecode, value}).
```

where typecode is a TC tuple and value is an Erlang term of the type defined by the typecode field.

Exports

- `create() -> Result`
- `create(Typecode, Value) -> Result`
  Types:
  - Typecode = TC
  - Value = term()
  - Result = Any

The create/0 function creates an empty any record and the create/2 function creates an initialized record.

- `set_typecode(A, Typecode) -> Result`
  Types:
  - A = Any
  - Typecode = TC
  - Result = Any

This function sets the typecode of A and returns a new any record.

- `get_typecode(A) -> Result`
  Types:
  - A = Any
  - Result = TC

Orber Application
This function returns the typecode of \( A \).

\[
\text{set\_value}(A, \text{Value}) \rightarrow \text{Result}
\]

Types:
- \( A = \text{Any} \)
- \( \text{Value} = \text{term()} \)
- \( \text{Result} = \text{Any} \)

This function sets the value of \( A \) and returns a new any record.

\[
\text{get\_value}(A) \rightarrow \text{Result}
\]

Types:
- \( A = \text{Any} \)
- \( \text{Result} = \text{term()} \)

This function returns the value of \( A \).
corba

Erlang Module

This module contains functions that are specified on the CORBA module level. It also contains some functions for creating and disposing objects.

Exports

create(Module, TypeID) -> Object
create(Module, TypeID, Env) -> Object
create(Module, TypeID, Env, Options1) -> Object
create_link(Module, TypeID) -> Object
create_link(Module, TypeID, Env) -> Object
create_link(Module, TypeID, Env, Options2) -> Reply

Types:
- Module = atom()
- TypeID = string()
- Env = term()
- Options1 = [{persistent, Bool} | {regname, RegName} | {local_typecheck, Bool}]
- Options2 = [{sup_child, Bool} | {persistent, Bool} | {regname, RegName} | {pseudo, Bool} | {local_typecheck, Bool}]
- RegName = {local, atom()} | {global, term()}
- Reply = #objref | {ok, Pid, #objref}
- Bool = true | false
- Object = #objref

These functions start a new server object. If you start it without RegName it can only be accessed through the returned object key. Started with a RegName the name is registered locally or globally.

TypeID is the repository ID of the server object type and could for example look like “IDL:StackModule/Stack:1.0”.

Module is the name of the interface API module.

Env is the arguments passed which will be passed to the implementations init call-back function.

A server started with create/2, create/3 or create/4 does not care about the parent, which means that the parent is not handled explicitly in the generic process part.

A server started with create_link2, create_link/3 or create_link/4 is initially linked to the caller, the parent, and it will terminate whenever the parent process terminates, and with the same reason as the parent. If the server traps exits, the terminate/2 call-back
function is called in order to clean up before the termination. These functions should be used if the server is a worker in a supervision tree.

If you use the option \{sup_child, true\} create_link/4 will return \{ok, Pid, #objref\}, otherwise #objref, and make it possible to start a server as a supervisor child (stdlib-1.7 or later).

If you use the option \{persistent, true\} you also must use the option \{regname, \{global, Name\}\}. This combination makes it possible to tell the difference between a server permanently terminated or in the process of restarting.

The option \{pseudo, true\}, allow us to create an object which is not a server. Using \{pseudo, true\} overrides all other start options. For more information see section Module Interface.

If a server is started using the option \{persistent, true\} the object key will not be removed unless it terminates with reason normal or shutdown. Hence, if persistent servers is used as supervisor childs they should be transient and the objectkeys.gc_time should be modified (default equals infinity).

The option \{local_typecheck, boolean()\}, which overrides the Local Typechecking environment flag, turns on or off typechecking. If activated, parameters, replies and raised exceptions will be checked to ensure that the data is correct, when invoking operations on CORBA Objects within the same Orber domain. Due to the extra overhead, this option MAY ONLY be used during testing and development.

Example:

```
  corba:create('StackModule_Stack', "IDL:StackModule/Stack:1.0", {10, test})
```

dispose(Object) -> ok

Types:

- \(\text{Object} = \#\text{objref}\)

This function is used for terminating the execution of a server object. Invoking this operation on a NIL object reference, e.g., the return value of \corba:create /\#\text{objref}/0, always return ok. For valid object references, invoking this operation more than once, will result in a system exception.

create-nil-object() -> Object

Types:

- \(\text{Object} = \#\text{objref}\) representing NIL.

Creates an object reference that represents the NIL value. Attempts to invoke operations using the returned object reference will return a system exception.

create-subobject-key(Object, Key) -> Result

Types:

- \(\text{Object} = \#\text{objref}\)
- \(\text{Key} = \text{term()}\)
- \(\text{Result} = \#\text{objref}\)
This function is used to create a subobject in a server object. It can for example be useful when one wants unique access to separate rows in a mnesia or an ETS table. The Result is an object reference that will be seen as a unique reference to the outside world but will access the same server object where one can use the `create_subobject_key/1` function to get the private key value.

Key is stored in the object reference `Object`. If it is a binary it will be stored as is and otherwise it is converted to a binary before storage.

```
get_subobject_key(Object) -> Result
```

Types:
- `Object = #objref`
- `Result = #binary`

This function is used to fetch a subobject key from the object reference `Object`. The result is a always a binary, if it was an Erlang term that was stored with `create_subobject_key/2` one can to do `binary_to_term/1` to get the real value.

```
get_pid(Object) -> Result
```

Types:
- `Object = #objref`
- `Result = #pid` | `error, Reason` | `'EXCEPTION', E`

This function is to get the process id from an object, which is a must when CORBA objects is started/handled in a supervisor tree. The function will throw exceptions if the key is not found or some other error occurs.

```
raise(Exception)
```

Types:
- `Exception = record()`

This function is used for raising corba exceptions as an Erlang user generated exit signal. It will throw the tuple `{'EXCEPTION', Exception}`.

```
reply(To, Reply) -> true
```

Types:
- `To = client reference`
- `Reply = IDL type`

This function can be used by a CORBA object to explicitly send a reply to a client that invoked a two-way operation. If this operation is used, it is not possible to return a reply in the callback module.

To must be the `From` argument provided to the callback function, which requires that the IC option from was used when compiling the IDL-file.

```
resolve_initial_references(ObjectId) -> Object
resolve_initial_references(ObjectId, Contexts) -> Object
```

Types:
- `ObjectId = string()`
- `Contexts = [Context]`
Orber Reference Manual

- Context = #IOP_ServiceContext' {context_id = CtxId, context_data = CtxData}
- CtxId = ?ORBER_GENERIC_CTX_ID
- CtxData = {interface, Interface} | {userspecific, term()}
- Interface = string()
- Object = #objref

This function returns the object reference associated with the given object id. Initially, only "NameService" is available. To add or remove services use `add_initial_service/2` or `remove_initial_service/1`.

`add_initial_service(ObjectId, Object) -> boolean()`

Types:
- ObjectId = string()
- Object = #objref

This operation allows us to add initial services, which can be accessed by using `resolve_initial_references/1` or the corbaloc schema. If using an Id defined by the OMG, the given object must be of the correct type; for more information see the Interoperable Naming Service [page 51]. Returns false if the given id already exists.

`remove_initial_service(ObjectId) -> boolean()`

Types:
- ObjectId = string()

If we don not want a certain service to be accessible, invoking this function will remove the association. Returns true if able to terminate the binding. If no such binding existed false is returned.

`list_initial_services() -> [ObjectId]`

Types:
- ObjectId = string()

This function returns a list of allowed object id's.

`resolve_initial_references_remote(ObjectId, Address) -> Object`

`resolve_initial_references_remote(ObjectId, Address, Contexts) -> Object`

Types:
- ObjectId = string()
- Address = [RemoteModifier]
- RemoteModifier = string()
- Contexts = [Context]
- Context = #IOP_ServiceContext' {context_id = CtxId, context_data = CtxData}
- CtxId = ?ORBER_GENERIC_CTX_ID
- CtxData = {interface, Interface} | {userspecific, term()}
- Interface = string()
- Object = #objref
This function returns the object reference for the object id asked for. The remote modifier string has the following format: "iiop://host:port".

**Warning:**
This operation is not supported by most ORB's. Hence, use corba:string_to_object/1 instead.

```plaintext
list_initial_services_remote(Address) -> [ObjectId]
list_initial_services_remote(Address, Contexts) -> [ObjectId]
```

**Types:**
- Address = [RemoteModifier]
- RemoteModifier = string()
- Contexts = [Context]
- Context = #IOP_ServiceContext'{context_id = CtxId, context_data = CtxData}
- CtxId = ?ORBER_GENERIC_CTX_ID
- CtxData = {interface, Interface} | {userspecific, term()}
- Interface = string()
- ObjectId = string()

This function returns a list of allowed object id's. The remote modifier string has the following format: "iiop://host:port".

**Warning:**
This operation is not supported by most ORB's. Hence, avoid using it.

```plaintext
object_to_string(Object) -> IOR_string
```

**Types:**
- Object = #objref
- IOR_string = string()

This function returns the object reference as the external string representation of an IOR.

```plaintext
string_to_object(IOR_string) -> Object
string_to_object(IOR_string, Contexts) -> Object
```

**Types:**
- IOR_string = string()
- Contexts = [Context]
- Context = #IOP_ServiceContext'{context_id = CtxId, context_data = CtxData}
- CtxId = ?ORBER_GENERIC_CTX_ID
- CtxData = {interface, Interface} | {userspecific, term()}
- Interface = string()
Object = #objref
This function takes a corbaname, corbaloc or an IOR on the external string representation and returns the object reference. To lookup the NameService reference, simply use "corbaloc:iiop:1.2@123.0.0.012:4001/NameService"
We can also resolve an object from the NameService by using "corbaname:iiop:1.2@123.0.0.012:4001/NameService#org/Erlang/MyObj"
For more information about corbaname and corbaloc, see the User's Guide (Interoperable Naming Service).
How to handle the interface context is further described in the User's Guide.

print_object(Data [, Type]) -> ok | {'EXCEPTION', E} | {'EXIT', R} | string()
Types:
- Data = IOR, string | #objref (local or external) | corbaloc/corbaname string
- Type = IoDevice | error_report | {error_report, Reason} | info_msg | {info_msg, Comment} | string
- IoDevice = see the io-module
- Reason = Comment = string()

The object represented by the supplied data is dissected and presented in a more readable form. The Type parameter is optional; if not supplied standard output is used. For error_report and info_msg the error_logger module is used, with or without Reason or Comment. If the atom string is supplied this function will return a flat list. The IoDevice is passed to the operation io:format/2.
If the supplied object is a local reference, the output is equivalent to an object exported from the node this function is invoked on.

add_alternate_iilop_address(Object, Host, Port) -> NewObject | {'EXCEPTION', E}
Types:
- Object = NewObject = local #objref
- Host = string()
- Port = integer()

This operation creates a new instance of the supplied object containing an ALTERNATE IIOP ADDRESS component. Only the new instance contains the new component. When this object is passed to another ORB, which supports the ALTERNATE IIOP ADDRESS, requests will be routed to the alternate address if it is not possible to communicate with the main address.
The ALTERNATE IIOP ADDRESS component requires that IIOP-1.2 is used. Hence, make sure both Orber and the other ORB is correctly configured.

Note:
Make sure that the given Object is accessible via the alternate Host/port. For example, if the object is correctly started as local or pseudo, the object should be available on all nodes within a multi-node Orber installation. Since only one instance exists for other object types, it will not be possible to access it if the node it was started on terminates.
corba Orber Reference Manual

orb_init(KeyValueList) -> ok | {'EXIT', Reason}

Types:
- KeyValueList = [{Key, Value}]
- Key = any key listed in the configuration chapter
- Value = allowed value associated with the given key

This function allows the user to configure Orber in, for example, an Erlang shell. Orber may NOT be started prior to invoking this operation. For more information, see configuration settings [page 14] in the User's Guide.
corba_object

Erlang Module

This module contains the CORBA Object interface functions that can be called for all objects.

Exports

get_interface(Object) -> InterfaceDef
Types:
- Object = #objref
- InterfaceDef = term()
This function returns the full interface description for an object.

is_nil(Object) -> boolean()
Types:
- Object = #objref
This function checks if the object reference has a nil object value, which denotes no object. It is the reference that is tested and no object implementation is involved in the test.

is_a(Object, Logical_type_id) -> Return
is_a(Object, Logical_type_id, Contexts) -> Return
Types:
- Object = #objref
- Logical_type_id = string()
- Contexts = [Context]
  - Context = #IOP_ServiceContext{context_id = CtxId, context_data = CtxData}
  - CtxId = #ORBER_GENERIC_CTX_ID
  - CtxData = {interface, Interface} | {userspecific, term()}
- Interface = string()
- Return = boolean() | {'EXCEPTION', E}
The Logical_type_id is a string that is a share type identifier (repository id). The function returns true if the object is an instance of that type or an ancestor of the “most derived” type of that object.

Note: Other ORB suppliers may not support this function completely according to the OMG specification. Thus, a is_a call may raise an exception or respond unpredictable if the object is located on a remote node.

**is_remote** (Object) -> boolean()

Types:
- Object = #objref

This function returns true if an object reference is remote otherwise false.

**non_existent** (Object) -> Return

**non_existent** (Object, Contexts) -> Return

Types:
- Object = #objref
- Contexts = [Context]
  - Context = #IOP_ServiceContext' { context_id = CtxId, context_data = CtxData }
  - CtxId = ?ORBER_GENERIC_CTX_ID
  - CtxData = { Interface, Interface } | { userspecific, term() }
  - Interface = string()
- Return = boolean() | { 'EXCEPTION', E }

This function can be used to test if the object has been destroyed. It does this without invoking any application level code. The ORB returns true if it knows that the object is destroyed otherwise false.

Note: The OMG have specified two different operators non_existent (CORBA version 2.0 and 2.2) and not_existent (CORBA version 2.3), to be used for this function. It is not mandatory to support both versions. Thus, a non_existent call may raise an exception or respond unpredictable if the object is located on a remote node. Depending on which version, ORB:s you intend to communicate with supports, you can either use this function or not_existent/1.

**not_existent** (Object) -> Return

**not_existent** (Object, Contexts) -> Return

Types:
- Object = #objref
- Contexts = [Context]
  - Context = #IOP_ServiceContext' { context_id = CtxId, context_data = CtxData }
  - CtxId = ?ORBER_GENERIC_CTX_ID
  - CtxData = { Interface, Interface } | { userspecific, term() }
  - Interface = string()
- Return = boolean() | { 'EXCEPTION', E }

This function is implemented due to Interoperable purposes. Behaves as non_existent except the operator not_existent is used when communicating with other ORB:s.

**is_equivalent** (Object, OtherObject) -> boolean()
Types:
- `Object = #objref`
- `OtherObject = #objref`

This function is used to determine if two object references are equivalent so far the ORB easily can determine. It returns `true` if the target object reference is equal to the other object reference and `false` otherwise.

```
hash(Object, Maximum) -> int()
```

Types:
- `Object = #objref`
- `Maximum = int()`

This function returns a hash value based on the object reference that not will change during the lifetime of the object. The `Maximum` parameter denotes the upper bound of the value.
This module contains functions that gives an interface to the CORBA fixed type. The type Fixed used below is defined as:

\[-record(fixed, \{digits, scale, value\}).\]

where digits is the total amount of digits it consists of and scale is the number of fractional digits. The value field contains the actual Fixed value represented as an integer. The limitations of each field are:

- **Digits** - integer(), \(-1 > Digits < 32\)
- **Scale** - integer(), \(-1 > Scale =< Digits\)
- **Value** - integer(), range (31 digits): \(99999999999999999999999999999999\)

Since the Value part is represented by an integer, it is vital that the Digits and Scale values are correct. This also means that trailing zeros cannot be left out in some cases:

- fixed<5,3> eq. 03.140d eq. 3140
- fixed<3,2> eq. 3.14d eq. 314

Leading zeros can be left out.

For your convenience, this module exports functions which handle unary (\(-\)) and binary (\(+\/-/\)) operations legal for the Fixed type. Since a unary + have no effect, this module do not export such a function. Any of the binary operations may cause an overflow (i.e. more than 31 significant digits; leading and trailing zeros are not considered significant). If this is the case, the Digit and Scale values are adjusted and the Value truncated (no rounding performed). This behavior is compliant with the OMG CORBA specification. Each binary operation have the following upper bounds:

- Fixed1 + Fixed2 - fixed<max(d1-s1,d2-s2) + max(s1,s2) + 1, max(s1,s2)>
- Fixed1 - Fixed2 - fixed<max(d1-s1,d2-s2) + max(s1,s2) + 1, max(s1,s2)>
- Fixed1 * Fixed2 - fixed<d1+d2, s1+s2>
- Fixed1 / Fixed2 - fixed<(d1-s1+s2) + Sinf ,Sinf >

A quotient may have an arbitrary number of decimal places, which is denoted by a scale of Sinf.
Exports

create(Digits, Scale, Value) -> Result

Types:
- Result = Fixed Type | {'EXCEPTION', '#BAD_PARAM'[]}

This function creates a new instance of a Fixed Type. If the limitations is not fulfilled (e.g. overflow) an exception is raised.

get_typecode(Fixed) -> Result

Types:
- Result = TypeCode | {'EXCEPTION', '#BAD_PARAM'[]}

Returns the TypeCode which represents the supplied Fixed type. If the parameter is not of the correct type, an exception is raised.

add(Fixed1, Fixed2) -> Result

Types:
- Result = Fixed1 + Fixed2 | {'EXCEPTION', '#BAD_PARAM'[]}

Performs a Fixed type addition. If the parameters are not of the correct type, an exception is raised.

subtract(Fixed1, Fixed2) -> Result

Types:
- Result = Fixed1 - Fixed2 | {'EXCEPTION', '#BAD_PARAM'[]}

Performs a Fixed type subtraction. If the parameters are not of the correct type, an exception is raised.

multiply(Fixed1, Fixed2) -> Result

Types:
- Result = Fixed1 * Fixed2 | {'EXCEPTION', '#BAD_PARAM'[]}

Performs a Fixed type multiplication. If the parameters are not of the correct type, an exception is raised.

divide(Fixed1, Fixed2) -> Result

Types:
- Result = Fixed1 / Fixed2 | {'EXCEPTION', '#BAD_PARAM'[]}

Performs a Fixed type division. If the parameters are not of the correct type, an exception is raised.

unary_minus(Fixed) -> Result

Types:
- Result = -Fixed | {'EXCEPTION', '#BAD_PARAM'[]}

Negates the supplied Fixed type. If the parameter is not of the correct type, an exception is raised.
interceptors

Erlang Module

This module contains the mandatory functions for user supplied native interceptors and their intended behaviour. See also the User's Guide.

**Warning:**
Using Interceptors may reduce the through-put significantly if the supplied interceptors invoke expensive operations. Hence, one should always supply interceptors which cause as little overhead as possible.

**Warning:**
It is possible to alter the Data, Bin and Args parameter for the in_reply and out_reply, in_reply_encoded, in_request_encoded, out_reply_encoded and out_request_encoded, in_request and out_request respectively. But, if it is done incorrectly, the consequences can be serious.

**Note:**
The Extra parameter is set to 'undefined' by Orber when calling the first interceptor and may be set to any erlang term. If an interceptor change this parameter it will be passed on to the next interceptor in the list uninterpreted.

**Note:**
The Ref parameter is set to 'undefined' by Orber when calling new_in_connection or new_out_connection using the first interceptor. The user supplied interceptor may set NewRef to any erlang term. If an interceptor change this parameter it will be passed on to the next interceptor in the list uninterpreted.
Exports

\texttt{new\_in\_connection(Ref, PeerHost, PeerPort) \rightarrow NewRef}
\texttt{new\_in\_connection(Ref, PeerHost, PeerPort, SocketHost, SocketPort) \rightarrow NewRef}

Types:
- \texttt{Ref = term() | undefined}
- \texttt{PeerHost = SocketHost = string(), e.g., “myHost@myServer” or “192.0.0.10”}
- \texttt{PeerPort = SocketPort = integer()}
- \texttt{NewRef = term() | ‘EXIT’, Reason}

When a new connection is requested by a client side ORB this operation is invoked. If more than one interceptor is supplied, e.g., \texttt{[native, ‘myInterceptor1’, ‘myInterceptor2’]}, the return value from ‘myInterceptor1’ is passed to ‘myInterceptor2’ as \texttt{Ref}. Initially, Orber uses the atom ‘undefined’ as \texttt{Ref} parameter when calling the first interceptor. The return value from the last interceptor, in the example above ‘myInterceptor2’, is passed to all other functions exported by the interceptors. Hence, the \texttt{Ref} parameter can, for example, be used as a unique identifier to mnesia or ets where information/restrictions for this connection is stored.

The PeerHost and PeerPort variables supplied data of the client ORB which requested a new connection. SocketHost and SocketPort are the local interface and port the client connected to.

If, for some reason, we do not allow the client ORB to connect simply invoke \texttt{exit(Reason)}.

\texttt{new\_out\_connection(Ref, PeerHost, PeerPort) \rightarrow NewRef}
\texttt{new\_out\_connection(Ref, PeerHost, PeerPort, SocketHost, SocketPort) \rightarrow NewRef}

Types:
- \texttt{Ref = term() | undefined}
- \texttt{PeerHost = SocketHost = string(), e.g., “myHost@myServer” or “192.0.0.10”}
- \texttt{PeerPort = SocketPort = integer()}
- \texttt{NewRef = term() | ‘EXIT’, Reason}

When a new connection is set up this function is invoked. Behaves just like \texttt{new\_in\_connection}; the only difference is that the PeerHost and PeerPort variables identifies the target ORB’s bootstrap data and SocketHost and SocketPort are the local interface and port the client ORB connected via.

\texttt{closed\_in\_connection(Ref) \rightarrow NewRef}

Types:
- \texttt{Ref = term()}
- \texttt{NewRef = term()}

When an existing connection is terminated this operation is invoked. The main purpose of this function is to make it possible for a user to clean up all data associated with the associated connection.

The input parameter \texttt{Ref} is the return value from \texttt{new\_in\_connection/3}.

\texttt{closed\_out\_connection(Ref) \rightarrow NewRef}
Types:
- Ref = term()
- NewRef = term()

When an existing connection is terminated this operation is invoked. The main purpose of this function is to make it possible for a user to clean up all data associated with the associated connection.

The input parameter Ref is the return value from new_out_connection/3.

\[
\text{in\_reply}(\text{Ref, Obj, Ctx, Op, Data, Extra}) \to \text{Reply}
\]

Types:
- Ref = term()
- Obj = #objref
- Ctx = [#IOP_ServiceContext']
- Op = atom()
- Data = [Result, OutParameter1, ..., OutParameterN]
- Reply = (NewData, NewExtra)

When replies are delivered from the server side ORB to the client side ORB this operation is invoked. The Data parameter is a list in which the first element is the return value value from the target object and the rest is a all parameters defined as out or inout in the IDL-specification.

\[
\text{in\_reply\_encoded}(\text{Ref, Obj, Ctx, Op, Bin, Extra}) \to \text{Reply}
\]

Types:
- Ref = term()
- Obj = #objref
- Ctx = [#IOP_ServiceContext']
- Op = atom()
- Bin = #binary
- Reply = (NewBin, NewExtra)

When replies are delivered from the server side ORB to the client side ORB this operation is invoked. The Bin parameter is the reply body still uncoded.

\[
\text{in\_request}(\text{Ref, Obj, Ctx, Op, Args, Extra}) \to \text{Reply}
\]

Types:
- Ref = term()
- Obj = #objref
- Ctx = [#IOP_ServiceContext']
- Op = atom()
- Args = [Argument] - defined in the IDL-specification
- Reply = (NewArgs, NewExtra)

When a new request arrives at the server side ORB this operation is invoked.

\[
\text{in\_request\_encoded}(\text{Ref, Obj, Ctx, Op, Bin, Extra}) \to \text{Reply}
\]

Types:
When a new request arrives at the server side ORB this operation is invoked before decoding the request body.

```
out_reply(Ref, Obj, Ctx, Op, Data, Extra) -> Reply
```

Types:
- Ref = term()
- Obj = #objref
- Ctx = [#IOP_ServiceContext{}]
- Op = atom()
- Bin = #binary
- Reply = {NewBin, NewExtra}

After the target object have been invoked this operation is invoked with the result. The Data parameter is a list in which the first element is the return value value from the target object and the rest is all parameters defined as out or inout in the IDL-specification.

```
out_reply_encoded(Ref, Obj, Ctx, Op, Bin, Extra) -> Reply
```

Types:
- Ref = term()
- Obj = #objref
- Ctx = [#IOP_ServiceContext{}]
- Op = atom()
- Bin = #binary
- Reply = {NewBin, NewExtra}

This operation is similar to `out_reply`; the only difference is that the reply body have been encoded.

```
out_request(Ref, Obj, Ctx, Op, Args, Extra) -> Reply
```

Types:
- Ref = term()
- Obj = #objref
- Ctx = [#IOP_ServiceContext{}]
- Op = atom()
- Args = [Argument] - defined in the IDL-specification
- Reply = {NewArgs, NewExtra}

Before a request is sent to the server side ORB, `out_request` is invoked.

```
out_request_encoded(Ref, Obj, Ctx, Op, Bin, Extra) -> Reply
```

Types:
- `Ref = term()`
- `Obj = #objref`
- `Ctx = [#IOP_ServiceContext'][]`
- `Op = atom()`
- `Bin = #binary`
- `Reply = {NewBin, NewExtra}`

This operation is similar to `out_request`; the only difference is that the request body have been encoded.
Iname

Erlang Module

This interface is a part of the names library which is used to hide the representation of names. In orbers Erlang mapping the pseudo-object names and the real IDL names have the same representation but it is desirable that the clients uses the names library so they will not be dependent of the representation. The Iname interface supports handling of names e.g. adding and removing name components.

Note that the Iname interface in orber does not contain a destroy function because the Names are represented as standard Erlang lists and therefor will be removed by the garbage collector when not in use.

The type NameComponent used below is defined as:

```
-record('CosNaming_NameComponent', {id, kind=""}).
```

id and kind are strings.

The record is defined in the file CosNaming.hrl and it is included with:

```
#include_lib("orber/COSS/CosNaming/CosNaming.hrl").
```

Exports

create() -> Return  
Types:  
• Return = [NameComponent]  
This function returns a new name.

insert_component(Name, N, NameComponent) -> Return  
Types:  
• Name = [NameComponent]  
• N = int()  
• Return = Name  
This function returns a name where the new name component has been inserted as component N in Name.

get_component(Name, N) -> Return  
Types:  
• Name = [NameComponent]  
• N = int()  
• Return = NameComponent
This function returns the $N$:th name component in Name.

delete_component(Name, N) -> Return

Types:
- Name = [NameComponent]
- N = int()
- Return = Name

This function deletes the $N$:th name component from Name and returns the new name.

num_components(Name) -> Return

Types:
- Name = [NameComponent]
- Return = int()

This function returns the number of name components in Name.

equal(Name1, Name2) -> Return

Types:
- Name1 = Name2 = [NameComponent]
- Return = bool()

This function returns true if the two names are equal and false otherwise.

less_than(Name1, Name2) -> Return

Types:
- Name1 = Name2 = [NameComponent]
- Return = bool()

This function returns true if Name1 are lesser than Name2 and false otherwise.

to_idl_form(Name) -> Return

Types:
- Name = [NameComponent]
- Return = Name

This function just checks if Name is a correct IDL name before returning it because the
name representation is the same for pseudo and IDL names in orber.

from_idl_form(Name) -> Return

Types:
- Name = [NameComponent]
- Return = Name

This function just returns the Name because the name representation is the same for
pseudo and IDL names in orber.
Iname_component

Erlang Module

This interface is a part of the name library, which is used to hide the representation of names. In orbers Erlang mapping the pseudo-object names and the real IDL names have the same representation but it is desirable that the clients uses the names library so they will not be dependent of the representation. The Iname_component interface supports handling of name components e.g. set and get of the struct members.

Note that the Iname_component interface in orber does not contain a destroy function because the NameComponents are represented as Erlang records and therefore will be removed by the garbage collector when not in use.

The type NameComponent used below is defined as:

\[-record('CosNaming_NameComponent', {id, kind=""}).\]

id and kind are strings.

The record is defined in the file CosNaming.hrl and it is included with:

\[-include_lib("orber/COSS/CosNaming/CosNaming.hrl").\]

Exports

create() -> Return

Types:
  • Return = NameComponent

This function returns a new name component.

get_id(NameComponent) -> Return

Types:
  • Return = string()

This function returns the id string of a name component.

set_id(NameComponent, Id) -> Return

Types:
  • Id = string()
  • Return = NameComponent

This function sets the id string of a name component and returns the component.

get_kind(NameComponent) -> Return
This function returns the id string of a name component.

```plaintext
get_id(NameComponent) -> Return
Types:
  • Return = string()
```

This function sets the kind string of a name component and returns the component.

```plaintext
set_kind(NameComponent, Kind) -> Return
Types:
  • Kind = string()
  • Return = NameComponent
```

This function returns the id string of a name component.
orber

Erlang Module

This module contains the functions for starting and stopping the application. It also has some utility functions to get some of the configuration information from running application.

Exports

\[
\text{start}() \rightarrow \text{ok} \\
\text{start}(	ext{Type}) \rightarrow \text{ok} \\
\]

Types:
- \text{Type} = \text{temporary} | \text{permanent}

Starts the Orber application (it also starts mnesia if it is not running). Which Type parameter is supplied determines the behavior. If not supplied Orber is started as temporary. See the Reference Manual application(3) for further information.

\[
\text{start}_\text{lightweight}() \rightarrow \text{ok} \\
\]

Starts the Orber application as lightweight.

Preconditions:
- Erlang started on the node using the option -orber lightweight, e.g., erl -orber lightweight Addresses
- The Addresses must be a list of RemoteModifiers, equal to the orber:resolve_initial_references remote/2 argument. The list must contain Orber nodes addresses, to which we have access and are not started as lightweight.

\[
\text{start}_\text{lightweight}(\text{Addresses}) \rightarrow \text{ok} \\
\]

Types:
- \text{Addresses} = [\text{Address}]
- \text{Address} = 
- \text{RetVal} = \text{ok} | \text{exit()}

Starts the Orber application as lightweight.

Preconditions:
- If Erlang is started using the configuration parameter -orber lightweight, e.g., erl -orber lightweight Address, the argument supplied to this function will override the configuration parameter. Hence, this function must be used carefully.
orber Reference Manual

- The Addresses must be a list of RemoteModifiers, equal to the orber:resolve_initial_references_remote/2 argument. The list must contain Orber nodes addresses to which we have access and are not started as lightweight.

`jump_start(Port) -> ok | {'EXIT', Reason}`

Types:
- `Port = integer()`

Installs and starts the Orber and the Mnesia applications with the configuration parameters `domain` and `iiop_port` set to "IP-number:Port" and the supplied `Port` respectively. Theses settings are in most cases sufficient to ensure that no clash with any other Orber instance occur. If this operation fails, check if the listen port (`iiop_port`) is already in use. This function MAY ONLY be used during development and tests; how Orber is configured when using this operation may change at any time without warning.

`stop() -> ok`

Stops the Orber application.

`info() -> ok`

`info(IoType) -> ok | {'EXIT', Reason} | string()`

Types:
- `IoType = info_msg | string | io | {io, IoDevice}`

Generates an Info Report, which contain Orber's configuration settings. If no `IoType` is supplied, `info_msg` is used (see the error_logger documentation). When the atom `string` is supplied this function will return a flat list. For `io` and `{io, IoDevice}`, `io:format/1` and `io:format/3` is used respectively.

`exception_info(Exception) -> {ok, string()} | {error, Reason}`

Returns a printable string, which describes the supplied exception in greater detail. Note, this function is mainly intended for system exceptions.

`is_lightweight() -> boolean()`

This function returns the true if Orber is started as lightweight, false otherwise.

`get_lightweight_nodes() -> RemoteModifierList | false`

This function returns false if Orber is not started as lightweight, otherwise a list of Remote Modifiers.

`get_tables() -> [Tables]`

Returns a list of the Orber specific Mnesia tables. This list is required to restore Mnesia if it has been partitioned.

`get_ORBInitRef() -> string() | undefined`
This function returns undefined if we will resolve references locally, otherwise a string
describing which host we will contact if the Key given to
corba:resolve_initial_references/1 matches the Key set in this configuration
variable. For more information see the user's guide.

get_ORBDefaultInitRef() -> string() | undefined

This function returns undefined if we will resolve references locally, otherwise a string
describing which host, or hosts, from which we will try to resolve the Key given to
corba:resolve_initial_references/1. For more information see the user's guide.

domain() -> string()

This function returns the domain name of the current Orber domain as a string.

iiop_port() -> int()

This function returns the port-number, which is used by the IIOP protocol. It can be
configured by setting the application variable iiop_port, if it is not set it will have the
default number 4001.

iiop_out_ports() -> 0 | {Min, Max}

The return value of this operation is what the configuration parameter iiop_out_ports
[page 14] have been set to.

iiop_ssl_port() -> int()

This function returns the port-number, which is used by the secure IIOP protocol. It
can be configured by setting the application variable iiop_ssl_port, if it is not set it will have the
default number 4002 if Orber is to configured to run in secure mode.
Otherwise it returns -1.

iiop_timeout() -> int() (milliseconds)

This function returns the timeout value after which outgoing IIOP requests terminate.
It can be configured by setting the application variable iiop_timeout TimeVal (seconds), if
it is not set it will have the default value infinity. If a request times out a system
exception, e.g. TIME OUT, is raised.

Note: the iiop_timeout configuration parameter (TimeVal) may only range between 0
and 1000000 seconds. Otherwise, the default value is used.

Note: Earlier IC versions required that the compile option
{timeout,"module::interface"}, was used, which allow the user to add an extra
timeout parameter, e.g., module::interface::function(ObjRef, Timeout, ... Arguments ...)
Of module::interface::function(ObjRef, [{timeout, Timeout}], ...
Arguments ...), instead of module::interface::function(ObjRef, ...
Arguments ...). This is no longer the case and if the extra Timeout is used, argument
will override the configuration parameter iiop_timeout. It is, however, not possible to
use infinity to override the Timeout parameter. The Timeout option is also valid for
objects which resides within the same Orber domain.

iiop_connection_timeout() -> int() (milliseconds)
This function returns the timeout value after which outgoing IIOP connections terminate. It can be configured by setting the application variable \texttt{iiop\_connection\_timeout TimeVal (seconds)}, if it is not set it will have the default value \texttt{infinity}. The connection will not be terminated if there are pending requests.

Note: the \texttt{iiop\_connection\_timeout} configuration parameter (TimeVal) may only range between 0 and 1000000 seconds. Otherwise, the default value is used.

\texttt{iiop\_connections()} \rightarrow \texttt{Result}

\texttt{iiop\_connections(\texttt{Direction})} \rightarrow \texttt{Result}

Types:
- \texttt{Direction = in | out | inout}
- \texttt{Result = [\{Host, Port\}] | [\{Host, Port, Interface\}] | \{'EXIT',Reason\}}
- \texttt{Host} = \texttt{string()}
- \texttt{Port} = \texttt{integer()}
- \texttt{Interface} = \texttt{string()}
- \texttt{Reason} = \texttt{term()}

The list returned by this operation contain tuples of remote hosts/ports Orber is currently connected to. If no \texttt{Direction} is not supplied, both incoming and outgoing connections are included.

If a specific local interface has been defined for the connection, this will be added to the returned tuple.

\texttt{iiop\_connections\_pending()} \rightarrow \texttt{Result}

Types:
- \texttt{Result = [\{Host, Port\}] | [\{Host, Port, Interface\}] | \{'EXIT',Reason\}}
- \texttt{Host} = \texttt{string()}
- \texttt{Port} = \texttt{integer()}
- \texttt{Interface} = \texttt{string()}
- \texttt{Reason} = \texttt{term()}

In some cases a connection attempt (i.e. trying to communicate with another ORB) may block due to a number of reasons. This operation allows the user to check if this is the case. The returned list contain tuples of remote hosts/ports. Normally, the list is empty.

If a specific local interface has been defined for the connection, this will be added to the returned tuple.

\texttt{iiop\_in\_connection\_timeout()} \rightarrow \texttt{int()} (milliseconds)

This function returns the timeout value after which incoming IIOP connections terminate. It can be configured by setting the application variable \texttt{iiop\_in\_connection\_timeout TimeVal (seconds)}, if it is not set it will have the default value \texttt{infinity}. The connection will not be terminated if there are pending requests.

Note: the \texttt{iiop\_in\_connection\_timeout} configuration parameter (TimeVal) may only range between 0 and 1000000 seconds. Otherwise, the default value is used.

\texttt{iiop\_acl()} \rightarrow \texttt{Result}

Types:
• Result = [{Direction, Filter}] | [{Direction, Filter, [Interface]}]
• Direction = tcp_in | ssl_in | tcp_out | ssl_out
• Filter = string()
• Interface = string()

Returns the ACL configuration. The Filter uses a extended format of Classless Inter Domain Routing (CIDR). For example, "123.123.123.10" limits the connection to that particular host, while "123.123.123.10/17" allows connections to or from any host equal to the 17 most significant bits. Orber also allow the user to specify a certain port or port range, for example, "123.123.123.10/17#4001" and "123.123.123.10/17#4001/5001" respectively. IPv4 or none compressed IPv6 strings are accepted.

The list of Interfaces, IPv4 or IPv6 strings, are currently only used for outgoing connections and may only contain one address. If set and access is granted, Orber will use that local interface when connecting to the other ORB. The module orber_acl [page 165] provides operations for evaluating the access control for filters and addresses.

activate_audit_trail() -> Result
activate_audit_trail(Verbosity) -> Result

Types:
• Verbosity = stealth | normal | verbose
• Result = ok | {error, Reason}
• Reason = string()

Activates audit/trail for all existing incoming and outgoing IIOP connections. The Verbosity parameter, stealth, normal or verbose, determines which of the built in interceptors is used (orber_iiopt_tracer_stealth, orber_iiopt_tracer_silent or orber_iiopt_tracerrespectively). If no verbosity level is supplied, then the normal will be used.

In case Orber is configured to use other interceptors, the audit/trail interceptors will simply be added to that list.

deactivate_audit_trail() -> Result

Types:
• Result = ok | {error, Reason}
• Reason = string()

Deactivates audit/trail for all existing incoming and outgoing IIOP connections. In case Orber is configured to use other interceptors, those will still be used.

add_listen_interface(IP, Type) -> Result
add_listen_interface(IP, Type, Port) -> Result

Types:
• IP = string
• Type = normal | ssl
• Port = integer() > 0
• Result = {ok, Ref} | {error, Reason} | {'EXCEPTIO N', E}
• Ref = #Ref
• E = #BAD_PARAM'{
Create a new process that handles requests for creating a new incoming IIOP connection via the given interface and port. If the latter is excluded, Orber will use the value of the iiop_port or iiop_ssl_port configuration parameters. The Type parameter determines if it is supposed to be IIOP or IIOP via SSL. If successful, the returned #Ref shall be passed to orber:remove:listen INTERFACE/1 when the connection shall be terminated.

If it is not possible to add a listener based on the supplied interface and port, the error message is one of the ones described in inet and/or ssl documentation.

**remove:listen INTERFACE(Ref) -> ok**

Types:
- Ref = #Ref

Terminates the listen process, associated with the supplied #Ref, for incoming a connection. The Ref parameter is the return value from the orber:add:listen INTERFACE/2/3 operation. When terminating the connection, all associated requests will not deliver a reply to the clients.

**secure() -> no | ssl**

This function returns the security mode Orber is running in, which is either no if it is an insecure domain or the type of security mechanism used. For the moment the only security mechanism is ssl. This is configured by setting the application variable secure.

**ssl_server_certfile() -> string()**

This function returns a path to a file containing a chain of PEM encoded certificates for the Orber domain as server. This is configured by setting the application variable ssl_server_certfile.

**ssl_client_certfile() -> string()**

This function returns a path to a file containing a chain of PEM encoded certificates used in outgoing calls in the current process. The default value is configured by setting the application variable ssl_client_certfile.

**set_ssl_client_certfile(Path) -> ok**

Types:
- Path = string()

This function takes a path to a file containing a chain of PEM encoded certificates as parameter and sets it for the current process.

**ssl_server_verify() -> 0 | 1 | 2**

This function returns the type of verification used by SSL during authentication of the other peer for incoming calls. It is configured by setting the application variable ssl_server_verify.

**ssl_client_verify() -> 0 | 1 | 2**
This function returns the type of verification used by SSL during authentication of the other peer for outgoing calls. The default value is configured by setting the application variable `ssl_client_verify`.

```
set_ssl_client_verify(Value) -> ok
Types:
  • Value = 0 | 1 | 2
```

This function sets the SSL verification type for the other peer of outgoing calls.

```
ssl_server_depth() -> int()
This function returns the SSL verification depth for incoming calls. It is configured by setting the application variable `ssl_server_depth`.
```

```
ssl_client_depth() -> int()
This function returns the SSL verification depth for outgoing calls. The default value is configured by setting the application variable `ssl_client_depth`.
```

```
set_ssl_client_depth(Depth) -> ok
Types:
  • Depth = int()
```

This function sets the SSL verification depth for the other peer of outgoing calls.

```
objectkeys_gc_time() -> int() (seconds)
This function returns the timeout value after which after which terminated object keys related to servers started with the configuration parameter `{persistent, true}`, will be removed. It can be configured by setting the application variable `objectkeys_gc_time TimeVal (seconds)`, if it is not set it will have the default value `infinity`.

Objects terminating with reason normal or shutdown are removed automatically.

Note: the `objectkeys_gc_time` configuration parameter (TimeVal) may only range between 0 and 1000000 seconds. Otherwise, the default value is used.
```

```
orber_nodes() -> RetVal
Types:
  • RetVal = [node()]
```

This function returns the list of node names that this orber domain consists of.

```
install(NodeList) -> ok
install(NodeList, Options) -> ok
Types:
  • NodeList = [node()]
  • Options = [Option]
    • Option = {install_timeout, Timeout} \ {ifr_storage_type, TableType} \ 
      {nameservice_storage_type, TableType} \ {initialreferences_storage_type, TableType}
    • Timeout = infinity \ integer()
```

This function sets the SSL verification depth for the other peer of outgoing calls.
orber

- **TableType = disc\_copies \| ram\_copies**

This function installs all the necessary mnesia tables and load default data in some of them. If one or more Orber tables already exists the installation fails. The function `uninstall` may be used, if it is safe, i.e., no other application is running Orber.

**Preconditions:**

- a mnesia schema must exist before the installation
- mnesia is running on the other nodes if the new installation shall be a multi node domain

Mnesia will be started by the function if it is not already running on the installation node and if it was started it will be stopped afterwards.

The options that can be sent to the installation program is:

- `{install\_timeout, Timeout}` - this timeout is how long we will wait for the tables to be created. The Timeout value can be infinity or an integer number in milliseconds. Default is infinity.
- `{ifr\_storage\_type, TableType}` - this option sets the type of tables used for the interface repository. The TableType can be `disc\_copies` or `ram\_copies`. Default is `disc\_copies`.
- `{initialreferences\_storage\_type, TableType}` - this option sets the type of table used for storing initial references. The TableType can be `disc\_copies` or `ram\_copies`. Default is `ram\_copies`.
- `{nameservice\_storage\_type, TableType}` - the default behavior of Orber is to install the NameService as `ram\_copies`. This option makes it possible to change this to `disc\_copies`. But the user should be aware of that if a node is restarted, all local object references stored in the NameService is not valid. Hence, you cannot switch to `disc\_copies` and expect exactly the same behavior as before.

`uninstall()` -> **ok**

This function stops the Orber application, terminates all server objects and removes all Orber related mnesia tables.

Note: Since other applications may be running on the same node using mnesia `uninstall` will not stop the mnesia application.

`add\_node(Node, Options) -> RetVal`

Types:

- `Node = node()`
- `Options = IFR\_StorageType \| KeyValue`
- `IFR\_StorageType = StorageType`
- `StorageType = disc\_copies \| ram\_copies`
- `KeyValue = {ifr\_storage\_type, StorageType} \| {initialreferences\_storage\_type, StorageType} \| {nameservice\_storage\_type, StorageType} \| {type, Type}`
- `Type = temporary \| permanent`
- `RetVal = ok \| exit()`
This function adds a given node to an existing Orber node group and starts Orber on the new node. `orber:add` is called from a member in the Orber node group.

Preconditions for new node:

- Erlang started on the new node using the option `-mnesia extra db nodes`, e.g.,
  `erl -sname new_node_name -mnesia extra db nodes ConnectToNodesList`
- The new node's domain name is the same for the nodes we want to connect to.
- Mnesia is running on the new node (no new schema created).
- If the new node will use `disc copies` the schema type must be changed using:
  `mnesia:change_table_copy_type(schema, node(), disc copies)`.

Orber will be started by the function on the new node.

Fails if:

- Orber already installed on given node.
- Mnesia not started as described above on the new node.
- Impossible to copy data in Mnesia tables to the new node.
- Not able to start Orber on the new node, due to, for example, the `iiop port` is already in use.

The function do not remove already copied tables after a failure. Use `orber:remove_node` to remove these tables.

```
remove_node(Node) -> RetVal

Types:
  - Node = node()
  - RetVal = ok | exit()
```

This function removes given node from a Orber node group. The Mnesia application is not stopped.

```
configure(Key, Value) -> ok | {'EXIT', Reason}

Types:
  - Key = orbDefaultInitRef | orbInitRef | giop_version | iiop_timeout | iiop_connection_timeout | iiop_setup_connection_timeout | iiop_in_connection_timeout | objectkeys_gc_time | orber_debug_level
  - Value = allowed value associated with the given key
```

This function allows the user to configure Orber in, for example, an Erlang shell. It is possible to invoke `configure` at any time the keys specified above.

Any other key must be set before installing and starting Orber.

Trying to change the configuration in any other way is NOT allowed since it may affect the behavior of Orber.

For more information regarding allowed values, see configuration settings [page 14] in the User's Guide.
**Note:**
Configuring the IIOP timeout values will not affect already existing connections. If you want a guaranteed uniform behavior, you must set these parameters from the start.
This module contains functions intended for analyzing Access Control List (ACL) filters. The filters use an extended format of Classless Inter Domain Routing (CIDR). For example, "123.123.123.10" limits the connection to that particular host, while "123.123.123.10/17" allows connections to or from any host equal to the 17 most significant bits. Orber also allows the user to specify a certain port or port range, for example, "123.123.123.10/17#4001" and "123.123.123.10/17#4001/5001" respectively. IPv4 or none compressed IPv6 strings are accepted.

Exports

match(IP, Direction) -> boolean()
match(IP, Direction, GetInfo) -> Reply

Types:
- IP = tuple() | [integer()]
- Direction = tcp_in | ssl_in | tcp_out | ssl_out
- GetInfo = boolean()
- Reply = boolean() | {boolean(), [Interface], PortInfo}
- Interface = string()
- PortInfo = integer() | {integer(), integer()}

If GetInfo is not supplied or set to false, this operation returns a boolean which tells if the IPv4 or IPv6 address would pass the ACL filter, defined by the iiop_acl configuration parameter, or not. When GetInfo is set to true, a tuple which, besides the boolean that tells if access was granted, also include the defined interfaces and port(s). This operation requires that Orber is running and can be used on a live node to determine if Orber has been properly configured.

verify(IP, Filter, Family) -> Reply

Types:
- IP = string()
- Filter = string()
- Family = inet | inet6
- Reply = true | {false, From, To} | {error, string()}
- From = string()
- To = string()
This operation returns true if the IPv4 or IPv6 address would pass the supplied ACL. If that is not the case, a tuple containing the accepted range is returned. This operation should only be used for test purposes.

range(Filter, Family) -> Reply

Types:
- Filter = string()
- Family = inet | inet6
- Reply = {ok, From, To} | {error, string()}
- From = string()
- To = string()

Returns the range of accepted IP addresses based on the supplied filter. This operation should only be used for test purposes.
Orber Reference Manual  

orber\_diagnostics

Erlang Module

This module contains functions which makes it possible to run simple tests.

Warning:
Functions exported by this module may only be used during test and development phase.

Exports

nameservice() -> Result
nameservice(Flags) -> Result

Types:
- Flags = integer()
- Result = ok | {'EXCEPTION', E}

Displays all objects stored in the NameService. Existent checks are, per default, also performed on all local objects. This can also be activated for external objects by setting the flag 16#01. The displayed information is the stringified Name described in CosNaming\_NamingContextExt [page 124], non existent status (true | false | external | undefined) and the IFR-Id:

host/
host/resources/
host/resources/MyObj/ [false] IDL:MyMod/MyIntf:1.0

missing\_modules() -> Count

Types:
- Count = integer()

This operation list missing modules generated by IC and required by Orber. Requires that all API:s are registered in the IFR.
This module contains functions for managing the Interface Repository (IFR). This documentation should be used in conjunction with the documentation in chapter 6 of CORBA 2.3. Whenever the term IFR object is used in this manual page, it refers to a pseudo object used only for interaction with the IFR rather than a CORBA object.

Initialisation of the IFR

The following functions are used to initialise the Interface Repository and to obtain the initial reference to the repository.

Exports

\[
\text{init}(\text{Nodes}, \text{Timeout}) \rightarrow \text{ok}
\]

Types:
- \text{Nodes} = \text{list()}
- \text{Timeout} = \text{integer()} \mid \text{infinity}

This function should be called to initialise the IFR. It creates the necessary mnesia-tables. A mnesia schema should exist, and mnesia must be running.

\[
\text{find_repository()} \rightarrow \text{#IFR_Repository_objref}
\]

Find the IFR object reference for the Repository. This reference should be used when adding objects to the IFR, and when extracting information from the IFR. The first time this function is called, it will create the repository and all the primitive definitions.

General methods

The following functions are the methods of the IFR. The first argument is always an #IFR_objref, i.e. the IFR (pseudo)object on which to apply this method. These functions are useful when the type of IFR object is not known, but they are somewhat slower than the specific functions listed below which only accept a particular type of IFR object as the first argument.
Exports

get_def_kind(Objref) -> Return

Types:
  • Objref = #IFR_object
  • Return = atom() (one of dk_none, dk_all, dk_Attribute, dk_Constant, dk_Exception,
    dk_Interface, dk_Module, dk_Operation, dk_Typedef, dk_Alias, dk_Struct, dk_Union,
    dk_Enum, dk_Primitive, dk_String, dk_Wstring, dk_Fixed, dk_Sequence, dk_Array,
    dk_Repository)
Objref is an IFR object of any kind. Returns the definition kind of the IFR object.

destroy(Objref) -> Return

Types:
  • Objref = #IFR_object
  • Return = tuple()
Objref is an IFR object of any kind except IRObject, Contained and Container. Destroys
that object and its contents (if any). Returns whatever mnesia:transaction returns.

get_id(Objref) -> Return

Types:
  • Objref = #IFR_object
  • Return = string()
Objref is an IFR object of any kind that inherits from Contained. Returns the repository
id of that object.

set_id(Objref,Id) -> ok

Types:
  • Objref = #IFR_object
  • Id = string()
Objref is an IFR object of any kind that inherits from Contained. Sets the repository id
of that object.

get_name(Objref) -> Return

Types:
  • Objref = #IFR_object
  • Return = string()
Objref is an IFR object of any kind that inherits from Contained. Returns the name of
that object.

set_name(Objref,Name) -> ok

Types:
  • Objref = #IFR_object
  • Name = string()
Objref is an IFR object of any kind that inherits from Contained. Sets the name of that object.

get_version(Objref) -> Return
Types:
- Objref = #IFR_object
- Return = string()

Objref is an IFR object of any kind that inherits from Contained. Returns the version of that object.

set_version(Objref,Version) -> ok
Types:
- Objref = #IFR_object
- Version = string()

Objref is an IFR object of any kind that inherits from Contained. Sets the version of that object.

get_defined_in(Objref) -> Return
Types:
- Objref = #IFR_object
- Return = #IFR_Container_objref

Objref is an IFR object of any kind that inherits from Contained. Returns the Container object that the object is defined in.

get_absolute_name(Objref) -> Return
Types:
- Objref = #IFR_object
- Return = string()

Objref is an IFR object of any kind that inherits from Contained. Returns the absolute (scoped) name of that object.

get_containing_repository(Objref) -> Return
Types:
- Objref = #IFR_object
- Return = #IFR_Repository_objref

Objref is an IFR object of any kind that inherits from Contained. Returns the Repository that is eventually reached by recursively following the object's defined_in attribute.

describe(Objref) -> Return
Types:
- Objref = #IFR_object
- Return = tuple() (a contained_description record) | {exception, _}
Objref is an IFR object of any kind that inherits from Contained. Returns a tuple describing the object.

```python
move(Objref, New_container, New_name, New_version) -> Return
```

Types:
- `Objref` = #IFR
- `New_container` = #IFR
- `New_name` = string()
- `New_version` = string()
- `Return` = ok | {exception, _}

Objref is an IFR object of any kind that inherits from Contained. New_container is an IFR object of any kind that inherits from Container. Removes Objref from its current Container, and adds it to New_container. The name attribute is changed to New_name and the version attribute is changed to New_version.

```python
lookup(Objref, Search_name) -> Return
```

Types:
- `Objref` = #IFR
- `Search_name` = string()
- `Return` = #IFR

Objref is an IFR object of any kind that inherits from Container. Returns an IFR object identified by search_name (a scoped name).

```python
contents(Objref, Limit_type, Exclude_inherited) -> Return
```

Types:
- `Objref` = #IFR
- `Limit_type` = atom() (one of dk_none, dk_all, dk_Attribute, dk_Constant, dk_Exception, dk_Interface, dk_Module, dk_Operation, dk_Typedef, dk_Alias, dk_Struct, dk_Union, dk_Enum, dk_Primitive, dk_String, dk_Wstring, dk_Fixed, dk_Sequence, dk_Array, dk_Repository)
- `Exclude_inherited` = atom() (true or false)
- `Return` = list() (a list of IFR#_objects)

Objref is an IFR object of any kind that inherits from Container. Returns the contents of that IFR object.

```python
lookup_name(Objref, Search_name, Levels_to_search, Limit_type, Exclude_inherited) -> Return
```

Types:
- `Objref` = #IFR
- `Search_name` = string()
- `Levels_to_search` = integer()
- `Limit_type` = atom() (one of dk_none, dk_all, dk_Attribute, dk_Constant, dk_Exception, dk_Interface, dk_Module, dk_Operation, dk_Typedef, dk_Alias, dk_Struct, dk_Union, dk_Enum, dk_Primitive, dk_String, dk_Wstring, dk_Fixed, dk_Sequence, dk_Array, dk_Repository)
- `Exclude_inherited` = atom() (true or false)
Return = list() (a list of #IFR objects)

Objref is an IFR object of any kind that inherits from Container. Returns a list of #IFR objects with an id matching Search.name.

describe_contents(Objref, Limit_type, Exclude_inherited, Max_returned_objs) -> Return
    Types:
        • Objref = #IFR objref
        • Limit_type = atom() (one of dk_none, dk_all, dk_Attribute, dk_Constant,
          dk_Exception, dk_Interface, dk_Module, dk_Operation, dk_Typedef, dk_Alias,
          dk_Struct, dk_Union, dk_Enum, dk_Primitive, dk_String, dk_WString, dk_Fixed,
          dk_Sequence, dk_Array, dk_Repository)
        • Exclude_inherited = atom() (true or false)
        • Return = list() (a list of tuples (contained, description records) | {exception, ...}

Objref is an IFR object of any kind that inherits from Container. Returns a list of descriptions of the IFR objects in this Container's contents.

create_module(Objref, Id, Name, Version) -> Return
    Types:
        • Objref = #IFR objref
        • Id = string()
        • Name = string()
        • Version = string()
        • Return = #IFR ModuleDef objref

Objref is an IFR object of any kind that inherits from Container. Creates an IFR object of the type ModuleDef.

create_constant(Objref, Id, Name, Version, Type, Value) -> Return
    Types:
        • Objref = #IFR objref
        • Id = string()
        • Name = string()
        • Version = string()
        • Type = #IFR IDLType objref
        • Value = any()
        • Return = #IFR ConstantDef objref

Objref is an IFR object of any kind that inherits from Container. Creates an IFR object of the type ConstantDef.

create_struct(Objref, Id, Name, Version, Members) -> Return
    Types:
        • Objref = #IFR objref
        • Id = string()
        • Name = string()
        • Version = string()
        • Members = list() (list of structmember records)
- Return = #FR_StructDef_objref
  Objref is an IFR object of any kind that inherits from Container. Creates an IFR object of the type StructDef.

create_union(Objref,Id,Name,Version,Discriminator,Type,Members) -> Return

Types:
- Objref = #FR_objref
- Id = string()
- Name = string()
- Version = string()
- Discriminator_Type = #FRIDLType_Objref
- Members = list() (list of unionmember records)
- Return = #FR_UnionDef_objref

Objref is an IFR object of any kind that inherits from Container. Creates an IFR object of the type UnionDef.

create_enum(Objref,Id,Name,Version,Members) -> Return

Types:
- Objref = #FR_objref
- Id = string()
- Name = string()
- Version = string()
- Members = list() (list of strings)
- Return = #FR_EnumDef_objref

Objref is an IFR object of any kind that inherits from Container. Creates an IFR object of the type EnumDef.

create_alias(Objref,Id,Name,Version,Original_Type) -> Return

Types:
- Objref = #FR_objref
- Id = string()
- Name = string()
- Version = string()
- Original_Type = #FRIDLType_Objref
- Return = #FR_AliasDef_objref

Objref is an IFR object of any kind that inherits from Container. Creates an IFR object of the type AliasDef.

create_interface(Objref,Id,Name,Version,Base_interfaces) -> Return

Types:
- Objref = #FR_objref
- Id = string()
- Name = string()
- Version = string()
- `Base_interfaces = list()` (a list of IFR.InterfaceDef.objrefs that this interface inherits from)
  - `Return = #IFR.InterfaceDef.objref`

Objref is an IFR object of any kind that inherits from Container. Creates an IFR object of the type InterfaceDef.

`create_exception(Objref, Id, Name, Version, Members) -> Return`

Types:
- `Objref = #IFR.objref`
- `Id = string()`
- `Name = string()`
- `Version = string()`
- `Members = list()` (list of structmember records)
- `Return = #IFR.ExceptionDef.objref`

Objref is an IFR object of any kind that inherits from Container. Creates an IFR object of the type ExceptionDef.

`get_type(Objref) -> Return`

Types:
- `Objref = #IFR.objref`
- `Return = tuple()` (a typecode tuple)

Objref is an IFR object of any kind that inherits from IDLType or an IFR object of the kind ConstantDef, ExceptionDef or AttributeDef. Returns the typecode of the IFR object.

`lookup_id(Objref, Search_id) -> Return`

Types:
- `Objref = #IFR.Repository.objref`
- `Search_id = string()`
- `Return = #IFR.objref`

Returns an IFR object matching the Search_id.

`get_primitive(Objref, Kind) -> Return`

Types:
- `Objref = #IFR.Repository.objref`
- `Kind = atom()` (one of pk_null, pk_void, pk_short, pk_long, pk_ushort, pk_ulong, pk_float, pk_double, pk_boolean, pk_char, pk_octet, pk_any, pk_TypeCode, pk_Principal, pk_string, pk_wstring, pk_fixed, pk_objref)
- `Return = #IFR.PrimitiveDef.objref`

Returns a PrimitiveDef of the specified kind.

`create_string(Objref, Bound) -> Return`

Types:
- `Objref = #IFR.Repository.objref`
• Bound = integer() (unsigned long /= 0)
• Return = #FR_StringDef_objref
  Creates an IFR objref of the type StringDef.

create_string(Objref, Bound) -> Return
  Types:
  • Objref = #FR_Repository_objref
  • Bound = integer() (unsigned long /= 0)
  • Return = #FR_WstringDef_objref
  Creates an IFR objref of the type WstringDef.

create_fixed(Objref, Digits, Scale) -> Return
  Types:
  • Objref = #FR_Repository_objref
  • Digits = Scale = integer()
  • Return = #FR_LFixedDef_objref
  Creates an IFR objref of the type FixedDef.

create_sequence(Objref, Bound, Element_type) -> Return
  Types:
  • Objref = #FR_Repository_objref
  • Bound = integer() (unsigned long)
  • Element_type = #FR_IDLType_objref
  • Return = #FR_SequenceDef_objref
  Creates an IFR objref of the type SequenceDef.

create_array(Objref, Length, Element_type) -> Return
  Types:
  • Objref = #FR_Repository_objref
  • Bound = integer() (unsigned long)
  • Element_type = #FR_IDLType_objref
  • Return = #FR_ArrayDef_objref
  Creates an IFR objref of the type ArrayDef.

create_idltype(Objref, Typecode) -> Return
  Types:
  • Objref = #FR_Repository_objref
  • Typecode = tuple() (a typecode tuple)
  • Return = #FR_IDLType_objref
  Creates an IFR objref of the type IDLType.

get_type_def(Objref) -> Return
  Types:
Objref = #IFR_objref
Return = #FR_IDLType_objref

Objref is an IFR object of the kind ConstantDef or AttributeDef. Returns an IFR object of the type IDLType describing the type of the IFR object.

**set_type_def(Objref,TypeDef) -> Return**

Types:
- Objref = #IFR_objref
- TypeDef = #FR_IDLType_objref
- Return = ok | {exception, _}

Objref is an IFR object of the kind ConstantDef or AttributeDef. Sets the type_def of the IFR Object.

**get_value(Objref) -> Return**

Types:
- Objref = #FR_ConstantDef_objref
- Return = any()

Returns the value attribute of an IFR Object of the type ConstantDef.

**set_value(Objref,Value) -> Return**

Types:
- Objref = #FR_ConstantDef_objref
- Value = any()
- Return = ok | {exception, _}

Sets the value attribute of an IFR Object of the type ConstantDef.

**get_members(Objref) -> Return**

Types:
- Objref = #IFR_objref
- Return = list()

Objref is an IFR object the kind StructDef, UnionDef, EnumDef or ExceptionDef. For StructDef, UnionDef and ExceptionDef: Returns a list of structmember records that are the constituent parts of the object. For EnumDef: Returns a list of strings describing the enumerations.

**set_members(Objref,Members) -> Return**

Types:
- Objref = #IFR_objref
- Members = list()
- Return = ok | {exception, _}
Objref is an IFR object the kind StructDef, UnionDef, EnumDef or ExceptionDef. For StructDef, UnionDef and ExceptionDef: Members is a list of structmember records. For EnumDef: Members is a list of strings describing the enumerations. Sets the members attribute, which are the constituent parts of the exception.

get_discriminator_type(Objref) -> Return

Types:
- Objref = #IFR_UnionDef_objref
  - Return = tuple() (a typecode tuple)

Returns the discriminator typecode of an IFR object of the type UnionDef.

get_discriminator_type_def(Objref) -> Return

Types:
- Objref = #IFR_UnionDef_objref
  - Return = #IFR_IDLType_objref

Returns an IFR object of the type IDLType describing the discriminator type of an IFR object of the type UnionDef.

set_discriminator_type_def(Objref,TypeDef) -> Return

Types:
- Objref = #IFR_UnionDef_objref
  - Return = #IFR_IDLType_objref

Sets the attribute discriminator_type_def, an IFR object of the type IDLType describing the discriminator type of an IFR object of the type UnionDef.

get_original_type_def(Objref) -> Return

Types:
- Objref = #FR_AliasDef_objref
  - Return = #FR_IDLType_objref

Returns an IFR object of the type IDLType describing the original type.

set_original_type_def(Objref,TypeDef) -> Return

Types:
- Objref = #FR_AliasDef_objref
  - Typedef = #FR_IDLType_objref
  - Return = ok | {exception, _}

Sets the original_type_def attribute which describes the original type.

get_kind(Objref) -> Return

Types:
- Objref = #FR_PrimitiveDef_objref
  - Return = atom()
Returns an atom describing the primitive type (See CORBA 2.0 p 6-21).

get_bound(Objref) -> Return

Types:
- Objref = #IFR_objref
- Return = integer (unsigned long)

Objref is an IFR object the kind StringDef or SequenceDef. For StringDef: returns the maximum number of characters in the string. For SequenceDef: Returns the maximum number of elements in the sequence. Zero indicates an unbounded sequence.

set_bound(Objref,Bound) -> Return

Types:
- Objref = #IFR_objref
- Bound = integer (unsigned long)
- Return = ok | exception

Objref is an IFR object the kind StringDef or SequenceDef. For StringDef: Sets the maximum number of characters in the string. Bound must not be zero. For SequenceDef: Sets the maximum number of elements in the sequence. Zero indicates an unbounded sequence.

get_element_type(Objref) -> Return

Types:
- Objref = #IFR_objref
- Return = tuple() (a typecode tuple)

Objref is an IFR object the kind SequenceDef or ArrayDef. Returns the typecode of the elements in the IFR object.

get_element_type_def(Objref) -> Return

Types:
- Objref = #IFR_objref
- Return = #IFR_IDLType_objref

Objref is an IFR object the kind SequenceDef or ArrayDef. Returns an IFR object of the type IDLType describing the type of the elements in Objref.

set_element_type_def(Objref,TypeDef) -> Return

Types:
- Objref = #IFR_objref
- TypeDef = #FR_IDLType_objref
- Return = ok | exception

Objref is an IFR object the kind StringDef or SequenceDef. Sets the element_type_def attribute, an IFR object of the type IDLType describing the type of the elements in Objref.

get_length(Objref) -> Return
Types:
- Objref = #IFR_ArrayDef_objref
- Return = integer() (unsigned long)

Returns the number of elements in the array.

\texttt{set\_length(Objref,Length) -> Return}

Types:
- Objref = #IFR_ArrayDef_objref
- Length = integer() (unsigned long)

Sets the number of elements in the array.

\texttt{get\_mode(Objref) -> Return}

Types:
- Objref = #IFR_objref
- Return = atom()

Objref is an IFR object the kind AttributeDef or OperationDef. For AttributeDef: Return is an atom ('ATTR\_NORMAL' or 'ATTR\_READONLY') specifying the read/write access for this attribute. For OperationDef: Return is an atom ('OP\_NORMAL' or 'OP\_ONEWAY') specifying the mode of the operation.

\texttt{set\_mode(Objref,Mode) -> Return}

Types:
- Objref = #IFR_objref
- Mode = atom()
- Return = ok | { exception, _ }

Objref is an IFR object the kind AttributeDef or OperationDef. For AttributeDef: Sets the read/write access for this attribute. Mode is an atom ('ATTR\_NORMAL' or 'ATTR\_READONLY'). For OperationDef: Sets the mode of the operation. Mode is an atom ('OP\_NORMAL' or 'OP\_ONEWAY').

\texttt{get\_result(Objref) -> Return}

Types:
- Objref = #IFR_OperationDef_objref
- Return = tuple() (a typecode tuple)

Returns a typecode describing the type of the value returned by the operation.

\texttt{get\_result\_def(Objref) -> Return}

Types:
- Objref = #IFR_OperationDef_objref
- Return = #IFR_IDLType_objref

Returns an IFR object of the type IDLType describing the type of the result.

\texttt{set\_result\_def(Objref,ResultDef) -> Return}
Types:
- Objref = #FR_OperationDef
- ResultDef = #FRIDLType
- Return = ok | { exception, _ }

Sets the type_def attribute, an IFR Object of the type IDLType describing the result.

get_params(Objref) -> Return
Types:
- Objref = #FR_OperationDef
- Return = list() (list of parameter description records)

Returns a list of parameter description records, which describes the parameters of the OperationDef.

set_params(Objref,Params) -> Return
Types:
- Objref = #FR_OperationDef
- Params = list() (list of parameter description records)
- Return = ok | { exception, _ }

Sets the params attribute, a list of parameter description records.

get_contexts(Objref) -> Return
Types:
- Objref = #FR_OperationDef
- Return = list() (list of strings)

Returns a list of context identifiers for the operation.

set_contexts(Objref,Contexts) -> Return
Types:
- Objref = #FR_OperationDef
- Contexts = list() (list of strings)
- Return = ok | { exception, _ }

Sets the context attribute for the operation.

get_exceptions(Objref) -> Return
Types:
- Objref = #FR_OperationDef
- Return = list() (list of #FR_ExceptionDef)

Returns a list of exception types that can be raised by this operation.

set_exceptions(Objref,Exceptions) -> Return
Types:
- Objref = #FR_OperationDef
- Exceptions = list() (list of #FR_ExceptionDef)
- Return = ok | {exception, _}
  Sets the exceptions attribute for this operation.

get_base_interfaces(Objref) -> Return

Types:
- Objref = #IFR.InterfaceDef_objref
- Return = list() (list of #IFR.InterfaceDef_objrefs)
Returns a list of InterfaceDefs from which this InterfaceDef inherits.

set_base_interfaces(Objref, BaseInterfaces) -> Return

Types:
- Objref = #IFR.InterfaceDef_objref
- BaseInterfaces = list() (list of #IFR.InterfaceDef_objrefs)
- Return = ok | {exception, _}
Sets the BaseInterfaces attribute.

is_a(Objref, Interface_id) -> Return

Types:
- Objref = #IFR.InterfaceDef_objref
- Interface_id = #IFR.InterfaceDef_objref
- Return = atom() (true or false)
Returns true if the InterfaceDef either is identical to or inherits from Interface_id.

describe_interface(Objref) -> Return

Types:
- Objref = #IFR.InterfaceDef_objref
- Return = tuple() (a full inter face description record)
Returns a full interface description record describing the InterfaceDef.

create_attribute(Objref, Id, Name, Version, Type, Mode) -> Return

Types:
- Objref = #IFR.InterfaceDef_objref
- Id = string()
- Name = string()
- Version = string()
- Type = #IFR.IDLType_objref
- Mode = atom() ('ATTR_NORMAL' or 'ATTR_READONLY')
- Return = #IFR.AttributeDef_objref
Creates an IFR object of the type AttributeDef contained in this InterfaceDef.

create_operation(Objref, Id, Name, Version, Result, Mode, Params, Exceptions, Contexts) -> Return

Types:
- Objref = #IFR_InterfaceDef_objref
- Id = string()
- Name = string()
- Version = string()
- Result = #IFRIDLType_objref
- Mode = atom() ('OP.NORMAL' or 'OP.ONEWAY')
- Params = list() (list of parameterdescription records)
- Exceptions = list() (list of #IFR_ExceptionDef_objrefs)
- Contexts = list() (list of strings)
- Return = #IFROperationDef_objref

Creates an IFR object of the type OperationDef contained in this InterfaceDef.
orber_tc

Erlang Module

This module contains some functions that gives support in creating IDL typecodes that can be used in for example the any types typecode field. For the simple types it is meaningless to use this API but the functions exist to get the interface complete.

The type TC used below describes an IDL type and is a tuple according to the to the Erlang language mapping.

Exports

null() -> TC
void() -> TC
short() -> TC
unsigned_short() -> TC
long() -> TC
unsigned_long() -> TC
long_long() -> TC
unsigned_long_long() -> TC
wchar() -> TC
float() -> TC
double() -> TC
boolean() -> TC
char() -> TC
octet() -> TC
any() -> TC
typecode() -> TC
principal() -> TC

These functions return the IDL typecodes for simple types.

object_reference(Id, Name) -> TC

Types:
- Id = string()
  the repository ID
- Name = string()
  the type name of the object

Function returns the IDL typecode for object_reference.

struct(Id, Name, ElementList) -> TC
Types:
- **Id** = string()
  the repository ID
- **Name** = string()
  the type name of the struct
- **ElementList** = [{**MemberName**, **TC**}]
  a list of the struct elements
- **MemberName** = string()
  the element name

Function returns the IDL typecode for struct.

union(Id, Name, DiscrTC, Default, ElementList) -> TC

Types:
- **Id** = string()
  the repository ID
- **Name** = string()
  the type name of the union
- **DiscrTC** = **TC**
  the typecode for the unions discriminant
- **Default** = integer()
  a value that indicates which tuple in the element list that is default (value < 0 means no default)
- **ElementList** = [{**Label**, **MemberName**, **TC**}]
  a list of the union elements
- **Label** = term()
  the label value should be of the **DiscrTC** type
- **MemberName** = string()
  the element name

Function returns the IDL typecode for union.

enum(Id, Name, ElementList) -> TC

Types:
- **Id** = string()
  the repository ID
- **Name** = string()
  the type name of the enum
- **ElementList** = [{**MemberName**}]
  a list of the enums elements
- **MemberName** = string()
  the element name

Function returns the IDL typecode for enum.

string(Length) -> TC

Types:
- **Length** = integer()
  the length of the string (0 means unbounded)
Function returns the IDL typecode for string.

**wstring(Length) -> TC**

Types:
- **Length** = integer()
  the length of the wstring (0 means unbounded)

Function returns the IDL typecode for wstring.

**fixed(Digits, Scale) -> TC**

Types:
- **Digits** = Scale = integer()
  the digits and scale parameters of a Fixed type

Function returns the IDL typecode for fixed.

**sequence(ElemTC, Length) -> TC**

Types:
- **ElemTC** = TC
  the typecode for the sequence elements
- **Length** = integer()
  the length of the sequence (0 means unbounded)

Function returns the IDL typecode for sequence.

**array(ElemTC, Length) -> TC**

Types:
- **ElemTC** = TC
  the typecode for the array elements
- **Length** = integer()
  the length of the array

Function returns the IDL typecode for array.

**alias(Id, Name, AliasTC) -> TC**

Types:
- **Id** = string()
  the repository ID
- **Name** = string()
  the type name of the alias
- **AliasTC** = TC
  the typecode for the type which the alias refer to

Function returns the IDL typecode for alias.

**exception(Id, Name, ElementList) -> TC**

Types:
- **Id** = string()
  the repository ID
- Name = string()
  the type name of the exception
- ElementList = [{MemberName, TC}]
  a list of the exception elements
- MemberName = string()
  the element name

Function returns the IDL typecode for exception.

get_tc(Object) -> TC
get_tc(Id) -> TC

Types:
- Object = record()
  an IDL specified struct, union or exception
- Id = string()
  the repository ID

If the get_tc/1 gets a record that is an IDL specified struct, union or exception as a parameter it returns the typecode.
If the parameter is a repository ID it uses the Interface Repository to get the typecode.

check_tc(TC) -> boolean()

Function checks the syntax of an IDL typecode.

Glossary

BindingIterator

The binding iterator (Like a book mark) indicates which objects have been read from the list.
Local for chapter 5.

CORBA

A specification of an architecture for a distributed object system

CORBA

Common Object Request Broker Architecture is a common communication standard developed by the
OMG (Object Management Group)
Local for chapter 2.

domains

A domain allows a more efficient communication protocol to be used between objects not on the same
node without the need of an ORB
Local for chapter 2.

IDL

Interface Definition Language - IDL is the OMG specified interface definition language, used to define
the CORBA object interfaces
Local for chapter 2.

IIOP

Internet-Inter ORB Protocol
Local for chapter 2.

IOR

Interoperable Object Reference
Local for chapter 1.
**Glossary**

**ORB**

Object Request Broker - ORB open software bus architecture specified by the OMG which allows object components to communicate in a heterogeneous environment. Local for chapter 2.

**Orber domain**

A domain containing several Erlang nodes, which are communicating by using the Erlang internal format. An Orber domain looks as one ORB from the environment. Local for chapter 3.

**Orber installation**

Is the structure of the ORB or ORBs as defined during the install process is called the “installation”. Local for chapter 3.

**Type Code**

Type Code is a full definition of a type Local for chapter 4.

**Type Codes**

Type codes give a complete description of the type including all its components and structure. Local for chapter 4.
