Inets User's Guide

The Inets Application provides a set of Internet related services. Currently supported are a HTTP client, a HTTP server and a ftp client.

1.1 Introduction

1.1.1 Purpose

Inets is a container for Internet clients and servers. Currently, an HTTP server, a FTP client and an HTTP client has been incorporated into Inets. The HTTP server and client is HTTP 1.1 compliant as defined in RFC 2616.

The HTTP client is now documented http(3) [page 49] and supported. It is loosely based on the earlier unsupported client developed by Johan Blom of Mobile Arts AB.

1.1.2 Prerequisites

It is assumed that the reader is familiar with the Erlang programming language, concepts of OTP and has a basic understanding of the HTTP and FTP protocols.

1.1.3 The Service Concept

Each client and server in inets is viewed as service. When starting the inets application the inets top supervisor will start a number of subsupervisors and worker processes for handling the different services provided. Some services require that there exist a configuration file, such as HTTP server(s), in order for the service(s) to be started. While the HTTP clients main process always will be started (it remains idle until some process issues a request) in this case the configuration is optional. Other services may not be configurable and have a more dynamic character, such as ftp clients, that will add worker processes to the supervision tree every time you do ftp:open/[1,2,3] an remove them every time you do ftp:close/1.

Services that needs configuring should be put into the inets applications configuration file on the form:

    [{inets, [{services, ListofConfiguredServices}]}].

For details of exactly what to put in the list of configured services see the documentation for the services that needs configuring.
1.2 FTP Client

1.2.1 Introduction

Ftp client processes exist only when you use them. When you open a ftp connection a client process will be spawned and added as a dynamic child to the ftp supervisor in the inets supervision tree. When you close the connection the client process will be terminated. Only the process that created the ftp-connection will be permitted to use it, and if that process dies the connection process will terminate. The client supports ipv6 as long as the underlying mechanisms also do so.

1.2.2 Using the FTP Client API

The following is a simple example of an ftp session, where the user guest with password password logs on to the remote host erlang.org, and where the file appl.erl is transferred from the remote to the local host. When the session is opened, the current directory at the remote host is /home/guest, and /home/fred at the local host. Before transferring the file, the current local directory is changed to /home/eproj/examples, and the remote directory is set to /home/guest/appl/examples.

```
1> application:start(inets).
ok
2> {ok, Pid} = ftp:open("erlang.org").
{ok,<0.22.0>}
3> ftp:user(Pid, "guest", "password").
oke
4> ftp:pwd(Pid).
{ok, "/home/guest"}
5> ftp:cd(Pid, "appl/examples").
oke
6> ftp:lpwd(Pid).
{ok, "/home/fred"}.
7> ftp:lcd(Pid, "/home/eproj/examples").
oke
8> ftp:recv(Pid, "appl.erl").
oke
9> ftp:close(Pid).
oke
```

1.3 HTTP Client

1.3.1 Introduction

The HTTP client will be started when the inets application is started and is then available to all processes on that erlang node. The client will spawn a new process to handle each request unless there is a possibility to pipeline a request. The client will add a host header and an empty te header if there are no such headers present in the request. The client supports ipv6 as long as the underlying mechanisms also do so.
1.3 Configuration

It is possible to configure what directory the HTTP client should use to store information. Currently the only information stored here is cookies. If the HTTP client service is not configured all cookies will be treated as session cookies. Here follows a description of a configuration entry for the HTTP client in the application configuration file.

```
[fnets, [fservices, [fhttpc, fProfile, Dir]]]]
```

Profile = atom() - default is the only valid value, as profiles are currently not supported.
Dir = string()

1.3.3 Using the HTTP Client API

1 > application:start(inets).
   ok

Use the proxy “www-proxy.mycompany.com:8000”, but not for requests to localhost. This will apply to all subsequent requests.

2 > http:set_options([[proxy, {"www-proxy.mycompany.com", 8000}, ["localhost"]])).
   ok

An ordinary synchronous request.

3 > {ok, {{Version, 200, ReasonPhrase}, Headers, Body}} =
   http:request(get, ["http://www.erlang.org"], [], []). With all default values, as above, a get request can also be written like this.

4 > {ok, {{Version, 200, ReasonPhrase}, Headers, Body}} =
   http:request("http://www.erlang.org").

An ordinary asynchronous request. The result will be sent to the calling process on the form {http, {RequestId, Result}}.

5 > {ok, RequestId} =
   http:request(get, ["http://www.erlang.org"], [], [], [{sync, false}]).

In this case the calling process is the shell, so we receive the result.

6 > receive {http, {RequestId, Result}} -> ok after 500 -> error end.
   ok

Send a request with a specified connection header.

7 > {ok, {{NewVersion, 200, NewReasonPhrase}, NewHeaders, NewBody}} =
   http:request(get, ["http://www.erlang.org", [{"connection", "close"}]], [], []).
1.4 HTTP server

1.4.1 Introduction

The HTTP server, also referred to as httpd, handles HTTP requests as described in RFC 2616 with a few exceptions such as gateway and proxy functionality. (The same is true for servers written by NCSA and others.) The server supports IPv6 as long as the underlying mechanisms also do so.

The server implements numerous features such as SSL (Secure Sockets Layer), ESI (Erlang Scripting Interface), CGI (Common Gateway Interface), User Authentication (using Mnesia, dets or plain text database), Common Logfile Format (with or without disk_log(3) support), URL Aliasing, Action Mappings, Directory Listings and SSI (Server-Side Includes).

The configuration of the server is done using Apache-style configuration directives.

Almost all server functionality has been implemented using an especially crafted server API, it is described in the Erlang Web Server API. This API can be used to advantage by all who wants to enhance the server core functionality, for example custom logging and authentication.

1.4.2 Basic Configuration

It is possible to start a number of Web servers in an embedded system using the services config parameter from an application config file. A minimal application config file (from now on referred to as inets.config) starting two HTTP servers typically looks as follows:

```
[{inets, [{services, [{httpd, "/var/tmp/server_root/conf/8888.conf"},
{httpd, "/var/tmp/server_root/conf/8080.conf"}]}]}
```

or:

```
[{inets, [{services, [{httpd, [{file, "/var/tmp/server_root/conf/8888.conf"}],
{httpd, [{file, "/var/tmp/server_root/conf/8080.conf"}]}}]}]}
```

according to a new syntax which allows more functionality in the configuration. The possible options here are a customer configurable request accept timeout, the default value is 15000 milliseconds, and some trace functionality to debug the http server. The syntax must match the following grammar:

```
httpd_service() -> {httpd,httpd()} 
httpd() -> [httpd_config()] | file() 
httpd_config() -> {file,file()}, 
{debug,debug()} ?,
{accept_timeout,integer()} ?
default() -> disable | [debug_options()] 
default_options() -> {all_functions,modules()} | 
{exported_functions,modules()} | 
{disable,modules()} 
modules() -> [atom()]
```
(file, file()) corresponds to the functionality of the old version.
(debug, debug()) is the new trace option. It can trace on all functions or only exported functions on
chosen modules.
(accept_timeout, integer()) sets the wanted timeout value for the server to set up a request connection.
A server config file is specified for each HTTP server to be started. The server config file syntax and
semantics is described in the runtime configuration section.
An easy way to test the setup of inets webservers can be done by copying the example server root
(UNIX: $INETS_ROOT/examples/server_root/conf/, Windows: %INETS_ROOT%\examples\server_root\conf\) to a specific installation directory
(/var/tmp/server_root/conf in this example). Then manually start the Erlang node, using inets.config.

```
$ erl -config ./inets
Erlang (BEAM) emulator version 4.9

Eshell V4.9 (abort with ^G) 1> application:start(inets).
ok
```

Now there should be two HTTP servers started listening on the ports 8888 and 8080. You can test it by
using any browser or the inets HTTP client requesting the urls: http://localhost:8888 and
http://localhost:8080

### 1.4.3 Server Runtime Configuration

All functionality in the server can be configured using Apache-style configuration directives stored in a
configuration file. A minimal configuration file could look something like:

```
ServerName web.server.net
ServerRoot /var/tmp/server_root
DocumentRoot /var/tmp/server_root/htdocs
```

E.g. the syntax is Directive followed by a whitespace followed by the value of the directive followed by a
new line.
The available directives are described in the section Server Configuration Directives

### 1.4.4 Server Configuration Directives

**Mandantory Directives**

- **DIRECTIVE**: “ServerName”
  Syntax: ServerName fully-qualified domain name
  Default: - Mandatory -
  ServerName sets the fully-qualified domain name of the server.

- **DIRECTIVE**: “ServerRoot”
  Syntax: ServerRoot directory-filename
  Default: - Mandatory -
  ServerRoot defines a directory-filename where the server has its operational home, e.g. used
to store log files and system icons. Relative paths specified in the config file refer to this
directory-filename.
Chapter 1: Inets User's Guide

- **DIRECTIVE:** “DocumentRoot”
  Syntax: DocumentRoot directory-filename
  Default: - Mandatory -
  DocumentRoot points the Web server to the document space from which to serve documents from. Unless matched by a directive like Alias, the server appends the path from the requested URL to the DocumentRoot to make the path to the document, for example:

  ```
  DocumentRoot /usr/web
  ```

  and an access to http://your.server.org/index.html would refer to /usr/web/index.html.

Communication Directives

- **DIRECTIVE:** “BindAddress”
  Syntax: BindAddress address
  Default: BindAddress *
  BindAddress defines which address the server will listen to. If the argument is * then the server listens to all addresses otherwise the server will only listen to the address specified. Address can be given either as an IP address or a hostname.

- **DIRECTIVE:** “Port”
  Syntax: Port number
  Default: Port 80
  Port defines which port number the server should use (0 to 65535). Certain port numbers are reserved for particular protocols, i.e. examine your OS characteristics\(^1\) for a list of reserved ports. The standard port for HTTP is 80.
  All ports numbered below 1024 are reserved for system use and regular (non-root) users cannot use them, i.e. to use port 80 you must start the Erlang node as root. (sic!) If you do not have root access choose an unused port above 1024 typically 8000, 8080 or 8888.

- **DIRECTIVE:** “SocketType”
  Syntax: SocketType type
  Default: SocketType ip_comm
  SocketType defines which underlying communication type to be used. Valid socket types are:
  - **ip_comm** the default and preferred communication type. ip_comm is also used for all remote message passing in Erlang.
  - **ssl** the communication type to be used to support SSL.

Limit Directives

- **DIRECTIVE:** “DisableChunkedTransferEncodingSend”
  Syntax: DisableChunkedTransferEncodingSend true | false
  Default: false
  This directive tells the server whether to use chunked transfer-encoding when sending a response to a HTTP/1.1 client.

- **DIRECTIVE:** “KeepAlive”
  Syntax: KeepAlive true | false
  Default: true
  This directive tells the server whether to use persistent connection or not when the client claims to be HTTP/1.1 compliant. Note the value of KeepAlive has changed from previous versions to be compliant with Apache.

\(^1\)In UNIX: /etc/services.
1.4: HTTP server

- **DIRECTIVE: “KeepAliveTimeout”**
  Syntax: KeepAliveTimeout seconds
  Default: 150
  The number of seconds the server will wait for a subsequent request from the client before closing the connection. If the load on the server is high you may want to shorten this.

- **DIRECTIVE: “MaxBodyAction”**
  Syntax: MaxBodyAction action
  Default: MaxBodyAction close
  MaxBodyAction specifies the action to be taken when the message body limit has been passed.

  - close: the default and preferred communication type. ip_comm is also used for all remote message passing in Erlang.
  - reply414: a reply (status) message with code 414 will be sent to the client prior to closing the socket. Note that this code is not defined in the HTTP/1.0 version of the protocol.

- **DIRECTIVE: “MaxBodySize”**
  Syntax: MaxBodySize size
  Default: MaxBodySize nolimit
  MaxBodySize limits the size of the message body of HTTP request. The reply to this is specified by the MaxBodyAction directive. Valid size is:

  - nolimit: the default message body limit, e.g. no limit.
  - integer(): any positive number.

- **DIRECTIVE: “MaxClients”**
  Syntax: MaxClients number
  Default: MaxClients 150
  MaxClients limits the number of simultaneous requests that can be supported. No more than this number of child server processes can be created.

- **DIRECTIVE: “MaxHeaderAction”**
  Syntax: MaxHeaderAction action
  Default: MaxHeaderAction close
  MaxHeaderAction specifies the action to be taken when the message Header limit has been passed.

  - close: the socket is closed without any message to the client. This is the default action.
  - reply414: a reply (status) message with code 414 will be sent to the client prior to closing the socket. Note that this code is not defined in the HTTP/1.0 version of the protocol.

- **DIRECTIVE: “MaxHeaderSize”**
  Syntax: MaxHeaderSize size
  Default: MaxHeaderSize 10240
  MaxHeaderSize limits the size of the message header of HTTP request. The reply to this is specified by the MaxHeaderAction directive. Valid size is:

  - integer(): any positive number (default is 10240)
  - nolimit: no limit should be applied

- **DIRECTIVE: “MaxKeepAliveRequests”**
  Syntax: MaxKeepAliveRequests NumberOfRequests
  Default: Disabled
  The number of request that a client can do on one connection. When the server has responded to the number of requests defined by MaxKeepAliveRequests the server close the connection. The server will close it even if there are queued request.
Administrative Directives

- **DIRECTIVE: “DefaultType”**
  Syntax: DefaultType mime-type
  Default: - None -
  When the server is asked to provide a document type which cannot be determined by the MIME Type Settings, the server must inform the client about the content type of documents and mime-type is used if an unknown type is encountered.

- **DIRECTIVE: “Modules”**
  Syntax: Modules module module ...
  Default: Modules mod_get mod_head mod_log
  Modules defines which Erlang Webserver API modules to be used in a specific server setup. module is a module in the code path of the server which has been written in accordance with the section Erlang Web Server API. The server executes functionality in each module, from left to right (from now on called Erlang Webserver API Module Sequence).
  Before altering the Erlang Webserver API Module Sequence please observe what types of data each module uses and propagates.

- **DIRECTIVE: “ServerAdmin”**
  Syntax: ServerAdmin email-address
  Default: ServerAdmin unknown@unknown
  ServerAdmin defines the email-address of the server administrator, to be included in any error messages returned by the server. It may be worth setting up a dedicated user for this because clients do not always state which server they have comments about, for example:

  ServerAdmin www-admin@white-house.com

SSL Directives

- **DIRECTIVE: “SSLCACertificateFile”**
  Syntax: SSLCACertificateFile filename
  Default: - None -
  SSLCACertificateFile points at a PEM encoded certificate of the certification authorities. Read more about PEM encoded certificates in the SSL application documentation.

- **DIRECTIVE: “SSLCertificateFile”**
  Syntax: SSLCertificateFile filename
  Default: - None -
  SSLCertificateFile points at a PEM encoded certificate. Read more about PEM encoded certificates in the SSL application documentation. The dummy certificate server.pem2, in the Inets distribution, can be used for test purposes.

- **DIRECTIVE: “SSLCertificateKeyFile”**
  Syntax: SSLCertificateKeyFile filename
  Default: - None -
  SSLCertificateKeyFile is used to point at a certificate key file. This directive should only be used if a certificate key has not been bundled with the certificate file pointed at by SSLCertificateFile.

- **DIRECTIVE: “SSLVerifyClient”**

\[2\text{In Windows: }%\text{INETS}\%\text{examples}\server \text{root}\ssl\. \text{In UNIX: }%\text{INETS}\%\text{examples}\server \text{root}/ssl/\]
SSLVerifyClient
Syntax: SSLVerifyClient type
Default: - None -
Set type to:

0 if no client certificate is required.
1 if the client may present a valid certificate.
2 if the client must present a valid certificate.
3 if the client may present a valid certificate but it is not required to have a valid CA.

Read more about SSL in the application documentation.

DIRECTIVE: “SSLVerifyDepth”
Syntax: SSLVerifyDepth integer
Default: - None -
This directive specifies how far up or down the (certification) chain we are prepared to go before giving up.
Read more about SSL in the application documentation.

DIRECTIVE: “SSLCipher”
Syntax: SSLCipher cipher
Default: - None -
SSLCipher is a colon separated list of ciphers.
Read more about SSL in the application documentation.

DIRECTIVE: “SSLPasswordCallbackFunction”
Syntax: SSLPasswordCallbackFunction function
Default: - None -
The SSLPasswordCallbackFunction function in module SSLPasswordCallbackModule is called in order to retrieve the user's password.
Read more about SSL in the application documentation.

DIRECTIVE: “SSLPasswordCallbackModule” Syntax: SSLPasswordCallbackModule function
Default: - None -
The SSLPasswordCallbackFunction function in the SSLPasswordCallbackModule module is called in order to retrieve the user's password.
Read more about SSL in the application documentation.

URL Aliasing

DIRECTIVE: “Alias”
Syntax: Alias url-path directory-filename
Default: - None -
The Alias directive allows documents to be stored in the local file system instead of the DocumentRoot location. URLs with a path that begins with url-path is mapped to local files that begins with directory-filename, for example:

Alias /image /ftp/pub/image

and an access to http://your.server.org/image/foo.gif would refer to the file /ftp/pub/image/foo.gif.

DIRECTIVE: “DirectoryIndex”
Syntax: DirectoryIndex file file ...
Default: - None -
Chapter 1: Inets User's Guide

DirectoryIndex specifies a list of resources to look for if a client requests a directory using a / at the end of the directory name. file depicts the name of a file in the directory. Several files may be given, in which case the server will return the first it finds, for example:

```conf
DirectoryIndex index.html
```

and access to http://your.server.org/docs/ would return http://your.server.org/docs/index.html if it existed.

- **DIRECTIVE:** "ScriptAlias"
  Syntax: ScriptAlias url-path directory-filename
  Default: None
  The ScriptAlias directive has the same behavior as the Alias directive, except that it also marks the target directory as containing CGI scripts. URLs with a path beginning with url-path are mapped to scripts beginning with directory-filename, for example:

```conf
ScriptAlias /cgi-bin/ /web/cgi-bin/
```

and an access to http://your.server.org/cgi-bin/foo would cause the server to run the script /web/cgi-bin/foo.

**CGI Directives**

- **DIRECTIVE:** "ScriptNoCache"
  Syntax: ScriptNoCache true | false
  Default: false
  If ScriptNoCache is set to true the Web server will by default add the header fields necessary to prevent proxies from caching the page. Generally this is something you want.

```conf
ScriptNoCache true
```

- **DIRECTIVE:** "ScriptTimeout"
  Syntax: ScriptTimeout Seconds
  Default: 15
  The time in seconds the web server will wait between each chunk of data from the script. If the CGI-script not delivers any data before the timeout the connection to the client will be closed.

```conf
ScriptTimeout 15
```

- **DIRECTIVE:** "Action"
  Syntax: Action mime-type cgi-script
  Default: None
  Action adds an action, which will activate a cgi-script whenever a file of a certain mime-type is requested. It propagates the URL and file path of the requested document using the standard CGI PATH_INFO and PATH_TRANSLATED environment variables.
  Examples:

```conf
Action text/plain /cgi-bin/log_and_deliver_text
Action home-grown/mime-type1 ~/bob/do_special_stuff
```
1.4: HTTP server

- **DIRECTIVE: “Script”**
  Syntax: Script method cgi-script
  Default: -None-
  Script adds an action, which will activate a cgi-script whenever a file is requested using a certain HTTP method. The method is either GET or POST as defined in RFC 1945. It propagates the URL and file path of the requested document using the standard CGI PATH_INFO and PATH_TRANSLATED environment variables.
  Examples:

  ```
  Script GET /cgi-bin/get
  Script POST /~bob/put_and_a_little_more
  ```

  **ESI Directives**

- **DIRECTIVE: “ErlScriptAlias”**
  Syntax: ErlScriptAlias url-path allowed-module allowed-module ...
  Default: -None-
  ErlScriptAlias marks all URLs matching url-path as erl scheme scripts. A matching URL is mapped into a specific module and function. The module must be one of the allowed-modules.
  For example:

  ```
  ErlScriptAlias /cgi-bin/hit_me httpd_example md4
  ```

  and a request to http://your.server.org/cgi-bin/hit_me/httpd_example:yahoo would refer to httpd_example:yahoo/2.

- **DIRECTIVE: “ErlScriptNoCache”**
  Syntax: ErlScriptNoCache true | false
  Default: false
  If ErlScriptNoCache is set to true the server will add http header fields that prevents proxies from caching the page. This is generally a good idea for dynamic content, since the content often vary between each request.

  ```
  ErlScriptNoCache true
  ```

- **DIRECTIVE: “EvalScriptAlias”**
  Syntax: EvalScriptAlias url-path allowed-module allowed-module ...
  Default: -None-

  Inets
EvalScriptAlias marks all URLs matching url-path as eval scheme scripts. A matching URL is mapped into a specific module and function. The module must be one of the allowed-modules.

For example:

```
EvalScriptAlias /cgi-bin/hit_me_to httpd_example md5
```

and a request to `http://your.server.org/cgi-bin/hit_me_to/httpd_example:print("Hi!")` would refer to `httpd_example:print/1`.

Auth Directives

- **DIRECTIVE**: "Directory"
  
  Syntax: `<Directory regexp-filename>`
  
  Default: - None -
  
  `<Directory>` and `/Directory>` are used to enclose a group of directives which applies only to the named directory and sub-directories of that directory. `regexp-filename` is an extended regular expression (See `regexp(3)`). For example:

  ```
  <Directory /usr/local/httpd[12]/htdocs>
  AuthAccessPassword s0MepA5wOrD
  AuthDBType plain
  AuthName My Secret Garden
  AuthUserFile /var/tmp/server_root/auth/user
  AuthGroupFile /var/tmp/server_root/auth/group
  require user ragnar edward
  require group group1
  allow from 123.145.244.5
  </Directory>
  ```

  If multiple directory sections match the directory (or its parents), then the directives are applied with the shortest match first. For example if you have one directory section for `garden/` and one for `garden/flowers`, the `garden/` section matches first.

- **DIRECTIVE**: "AuthDBType"
  
  Syntax: `AuthDBType plain | dets | mnesia`
  
  Default: - None -
  
  Context: Directory
  
  `AuthDBType` sets the type of authentication database that is used for the directory. The key difference between the different methods is that dynamic data can be saved when Mnesia and Dets is used.

  If Mnesia is used as storage method, Mnesia must be started prior to the webserver. The first time Mnesia is started the schema and the tables must be created before Mnesia is started. A naive example of a module with two functions that creates and start mnesia is provided here. The function shall be sued the first time. `first_start/0` creates the schema and the tables. The second function `start/0` shall be used in consecutive startups. `start/0` starts Mnesia and wait for the tables to be initiated. This function must only be used when the schema and the tables already is created.

  ```
  -module(mnesia_test).
  -export([start/0, load_data/0]).
  -include("mod_auth.hrl").
  ```
To create the Mnesia tables we use two records defined in mod_auth.hrl so the file must be included.

The first function `first_start/0` creates a schema that specify on which nodes the database shall reside. Then it starts Mnesia and creates the tables. The first argument is the name of the tables, the second argument is a list of options how the table will be created, see Mnesia documentation for more information. Since the current implementation of the mod_auth.mnesia saves one row for each user the type must be bag.

When the schema and the tables is created the second function `start/0` shall be used to start Mnesia. It starts Mnesia and wait for the tables to be loaded. Mnesia use the directory specified as `mnesia_dir` at startup if specified, otherwise Mnesia use the current directory.

For security reasons, make sure that the Mnesia tables are stored outside the document tree of the Web server. If it is placed in the directory which it protects, clients will be able to download the tables.

Only the dets and mnesia storage methods allow writing of dynamic user data to disk. plain is a read only method.

- **DIRECTIVE: “AuthUserFile”**
  Syntax: AuthUserFile filename
  Default: - None -
  Context: Directory
  AuthUserFile sets the name of a file which contains the list of users and passwords for user authentication. filename can be either absolute or relative to the `ServerRoot`.
  If using the plain storage method, this file is a plain text file, where each line contains a user name followed by a colon, followed by the non-encrypted password. The behavior is undefined if user names are duplicated. For example:

  ```
  ragnar:s7Xxv7
  edward:wwjau8
  ```

  If using the dets storage method, the user database is maintained by `dets` and should not be edited by hand. Use the API functions in mod_auth module to create / edit the user database.
  This directive is ignored if using the mnesia storage method.
  For security reasons, make sure that the AuthUserFile is stored outside the document tree of the Web server. If it is placed in the directory which it protects, clients will be able to download it.

- **DIRECTIVE: “AuthGroupFile”**
  Syntax: AuthGroupFile filename
  Default: - None -
Context: Directory
AuthGroupFile sets the name of a file which contains the list of user groups for user authentication. filename can be either absolute or relative to the ServerRoot.
If you use the plain storage method, the group file is a plain text file, where each line contains a group name followed by a colon, followed by the member user names separated by spaces. For example:

    group1: bob joe ante

If using the dets storage method, the group database is maintained by dets and should not be edited by hand. Use the API for mod_auth module to create / edit the group database.
This directive is ignored if using the mnesia storage method.
For security reasons, make sure that the AuthGroupFile is stored outside the document tree of the Web server. If it is placed in the directory which it protects, clients will be able to download it.

- **DIRECTIVE: “AuthName”**
  Syntax: AuthName auth-domain
  Default: - None -
  Context: Directory
  AuthName sets the name of the authorization realm (auth-domain) for a directory. This string informs the client about which user name and password to use.

- **DIRECTIVE: “AuthAccessPassword”**
  Syntax: AuthAccessPassword password
  Default: NoPassword
  Context: Directory
  If AuthAccessPassword is set to other than NoPassword the password is required for all API calls.
  If the password is set to DummyPassword the password must be changed before any other API calls. To secure the authenticating data the password must be changed after the webserver is started since it otherwise is written in clear text in the configuration file.

- **DIRECTIVE: “allow”**
  Syntax: allow from host host ...
  Default: allow from all
  Context: Directory
  allow defines a set of hosts which should be granted access to a given directory. host is one of the following:

    all  All hosts are allowed access.

    A regular expression (Read regexp(3)) All hosts having a numerical IP address matching the specific regular expression are allowed access.

  For example:

    allow from 123.34.56.11 150.100.23

  The host 123.34.56.11 and all machines on the 150.100.23 subnet are allowed access.

- **DIRECTIVE: “deny”**
  Syntax: deny from host host ...
  Default: deny from all
  Context: Directory
  deny defines a set of hosts which should not be granted access to a given directory. host is one of the following:
1.4: HTTP server

all  All hosts are denied access.

A regular expression (Read regexp(3))  All hosts having a numerical IP address matching the specific regular expression are denied access.

For example:

deny from 123.34.56.11 150.100.23

The host 123.34.56.11 and all machines on the 150.100.23 subnet are denied access.

- **DIRECTIVE:** “require”
  Syntax: require entity-name entity entity ...
  Default: - None -
  Context: Directory
  require defines users which should be granted access to a given directory using a secret password.
  The allowed syntaxes are:

  ```
  require user user-name user-name ...  Only the named users can access the directory.
  require group group-name group-name ...  Only users in the named groups can access the directory.
  ```

Htacess Authentication Directives

- **DIRECTIVE:** “AccessFileName” Syntax: AccessFileName FileName1 FileName2
  Default: .htaccess
  Context: Directory
  AccessFileName Specify which filenames that are used for access-files. When a request comes every directory in the path to the requested asset will be searched after files with the names specified by this parameter. If such a file is found the file will be parsed and the restrictions specified in it will be applied to the request.

Auth Filter Directives

- **DIRECTIVE:** “SecurityDataFile”
  Syntax: SecurityDataFile filename
  Default: - None -
  Context: Directory
  SecurityDataFile sets the name of the security modules for a directory. The filename can be either absolute or relative to the ServerRoot. This file is used to store persistent data for the mod_security module.
  Several directories can have the same SecurityDataFile.

- **DIRECTIVE:** “SecurityMaxRetries”
  Syntax: SecurityMaxRetries integer() | infinity
  Default: 3
  Context:
  SecurityMaxRetries specifies the maximum number of tries to authenticate a user has before he is blocked out. If a user successfully authenticates when he is blocked, he will receive a 403 (Forbidden) response from the server.
  For security reasons, failed authentications made by this user will return a message 401 (Unauthorized), even if the user is blocked.

- **DIRECTIVE:** “SecurityBlockTime”
  Syntax: SecurityBlockTime integer() | infinity

Inets 15
Chapter 1: Inets User’s Guide

Default: 60
Context: Directory

SecurityBlockTime specifies the number of minutes a user is blocked. After this amount of time, he automatically regains access.

- **DIRECTIVE:** “SecurityFailExpireTime”
  Syntax: SecurityFailExpireTime integer() | infinity
  Default: 30
  Context: Directory
  SecurityFailExpireTime specifies the number of minutes a failed user authentication is remembered. If a user authenticates after this amount of time, his previous failed authentications are forgotten.

- **DIRECTIVE:** “SecurityAuthTimeout”
  Syntax: SecurityAuthTimeout integer() | infinity
  Default: 30
  Context: Directory
  SecurityAuthTimeout specifies the number of seconds a successful user authentication is remembered. After this time has passed, the authentication will no longer be reported.

- **DIRECTIVE:** “SecurityCallbackModule”
  Syntax: SecurityCallbackModule atom()
  Default: None
  Context: Directory
  SecurityCallbackModule specifies the name of a callback module.

Logging Directives

- **DIRECTIVE:** “ErrorLog”
  Syntax: ErrorLog filename
  Default: None
  ErrorLog defines the filename of the error log file to be used to log server errors. If the filename does not begin with a slash (/) it is assumed to be relative to the ServerRoot, for example:

  ErrorLog logs/error_log_8080

  and errors will be logged in the server root space.

- **DIRECTIVE:** “SecurityLog”
  Syntax: SecurityLog filename
  Default: None
  SecurityLog defines the filename of the access log file to be used to log security events. If the filename does not begin with a slash (/) it is assumed to be relative to the ServerRoot. For example:

  SecurityLog logs/security_log_8080

  and security events will be logged in the server root space.

- **DIRECTIVE:** “TransferLog”
  Syntax: TransferLog filename
  Default: None

---

3In Windows: %SERVER\ROOT%\logs\error_log_8080. In UNIX: $SERVER_ROOT/logs/error_log_8080.
TransferLog defines the filename of the access log file to be used to log incoming requests. If the filename does not begin with a slash (/) it is assumed to be relative to the ServerRoot. For example:

```
TransferLog logs/access_log_8080
```

and errors will be logged in the server root\(^5\) space.

**Disk Log Directives**

- **DIRECTIVE: “DiskLogFormat”**
  Syntax: DiskLogFormat internal | external
  Default: - external -

  DiskLogFormat defines the file-format of the log files see disk_log for more information. If the internal file-format is used, the log file will be repaired after a crash. When a log file is repaired data might get lost. When the external file-format is used httpd will not start if the log file is broken.

```
DiskLogFormat external
```

- **DIRECTIVE: “ErrorDiskLog”**
  Syntax: ErrorDiskLog filename
  Default: - None -

  ErrorDiskLog defines the filename of the (disk_log(3)) error log file to be used to log server errors. If the filename does not begin with a slash (/) it is assumed to be relative to the ServerRoot, for example:

```
ErrorDiskLog logs/error_disk_log_8080
```

and errors will be logged in the server root\(^6\) space.

- **DIRECTIVE: “ErrorDiskLogSize”**
  Syntax: ErrorDiskLogSize max-bytes max-files
  Default: ErrorDiskLogSize 512000 8

  ErrorDiskLogSize defines the properties of the (disk_log(3)) error log file. The disk_log(3) error log file is of type wrap log and max-bytes will be written to each file and max-files will be used before the first file is truncated and reused.

- **DIRECTIVE: “SecurityDiskLog”**
  Syntax: SecurityDiskLog filename
  Default: - None -

  SecurityDiskLog defines the filename of the (disk_log(3)) access log file which logs incoming security events i.e authenticated requests. If the filename does not begin with a slash (/) it is assumed to be relative to the ServerRoot.

- **DIRECTIVE: “SecurityDiskLogSize”**
  Syntax: SecurityDiskLogSize max-bytes max-files
  Default: SecurityDiskLogSize 512000 8

SecurityDiskLogSize defines the properties of the disk_log(3) access log file. The disk_log(3) access log file is of type wrap log and max-bytes will be written to each file and max-files will be used before the first file is truncated and reused.

- **DIRECTIVE:** "TransferDiskLog"
  Syntax: TransferDiskLog filename
  Default: - None -
  TransferDiskLog defines the filename of the (disk_log(3)) access log file which logs incoming requests. If the filename does not begin with a slash (/) it is assumed to be relative to the ServerRoot, for example:

  ```
  TransferDiskLog logs/transfer_disk_log_8080
  ```

  and errors will be logged in the server root space.

- **DIRECTIVE:** "TransferDiskLogSize"
  Syntax: TransferDiskLogSize max-bytes max-files
  Default: TransferDiskLogSize 512000 8
  TransferDiskLogSize defines the properties of the disk_log(3) access log file. The disk_log(3) access log file is of type wrap log and max-bytes will be written to each file and max-files will be used before the first file is truncated and reused.

1.4.5 Mime Type Configuration

Files delivered to the client are MIME typed according to RFC 1590. File suffixes are mapped to MIME types before file delivery.

The mapping between file suffixes and MIME types are specified in the mime.types file. The mime.types reside within the conf directory of the ServerRoot. MIME types may be added as required to the mime.types file and the DefaultType config directive can be used to specify a default mime type.

An example of a very small mime.types file:

```text
# MIME type     Extension
text/html    html htm
text/plain   asc txt
```

1.4.6 Htaccess - User Configurable Authentication.

If users of the webserver needs to manage authentication of webpages that are local to their user and do not have server administrative privileges. They can use the per-directory runtime configurable user-authentication scheme that Inets calls htaccess. It works the following way:

- Each directory in the path to the requested asset is searched for an access-file (default .htaccess), that restricts the webserver’s rights to respond to a request. If an access-file is found the rules in that file is applied to the request.
- The rules in an access-file applies both to files in the same directories and in subdirectories. If there exists more than one access-file in the path to an asset, the rules in the access-file nearest the requested asset will be applied.
- To change the rules that restricts the use of an asset. The user only needs to have write access to the directory where the asset exists.

---

7In Windows: %SERVER\ROOT%\logs\transfer_disk_log_8080. In UNIX: $SERVER\ROOT/logs/transfer_disk_log_8080.
All the access-files in the path to a requested asset is read once per request, this means that the load on the server will increase when this scheme is used.

If a directory is limited both by auth directives in the HTTP server configuration file and by the .htaccess files. The user must be allowed to get access the file by both methods for the request to succeed.

Access Files Directives

In every directory under the DocumentRoot or under an Alias a user can place an access-file. An access-file is a plain text file that specify the restrictions that shall be considered before the webserver answer to a request. If there are more than one access-file in the path to the requested asset, the directives in the access-file in the directory nearest the asset will be used.

- **DIRECTIVE: “allow” Syntax:** Allow from subnet subnet | from all
  - **Default:** from all
  - Same as the directive allow for the server config file.

- **DIRECTIVE: “AllowOverRide” Syntax:** AllowOverRide all | none | Directives
  - **Default:** None
  - AllowOverRide Specify which parameters that not access-files in subdirectories are allowed to alter the value for. If the parameter is set to none no more access-files will be parsed.
  - If only one access-file exists setting this parameter to none can lessen the burden on the server since the server will stop looking for access-files.

- **DIRECTIVE: “AuthGroupfile” Syntax:** AuthGroupFile Filename
  - **Default:** None
  - AuthGroupFile indicates which file that contains the list of groups. Filename must contain the absolute path to the file. The format of the file is one group per row and every row contains the name of the group and the members of the group separated by a space, for example:

  
  GroupName: Member1 Member2 .... MemberN

- **DIRECTIVE: “AuthName” Syntax:** AuthName auth-domain
  - **Default:** None
  - Same as the directive AuthName for the server config file.

- **DIRECTIVE: “AuthType” Syntax:** AuthType Basic
  - **Default:** Basic
  - AuthType Specify which authentication scheme that shall be used. Today only Basic Authenticating using UUEncoding of the password and user ID is implemented.

- **DIRECTIVE: “AuthUserFile” Syntax:** AuthUserFile Filename
  - **Default:** None
  - AuthUserFile indicate which file that contains the list of users. Filename must contain the absolute path to the file. The format of the file is one user per row and every row contains UserName and Password separated by a colon, for example:

  
  UserName:Password
  UserName:Password

- **DIRECTIVE: “deny” Syntax:** deny from subnet subnet | from all
  - **Context:** Limit
Same as the directive deny for the server config file.

- **DIRECTIVE:** “Limit”  
  Syntax: `<Limit RequestMethods>`  
  Default: - None -  
  `<Limit>` and `</Limit>` are used to enclose a group of directives which applies only to requests using the specified methods. If no request method is specified all request methods are verified against the restrictions.

```plaintext
<Limit POST GET HEAD>
order allow deny
require group group1
allow from 123.145.244.5
</Limit>
```

- **DIRECTIVE:** “order”  
  Syntax: `order allow deny | deny allow`  
  Default: allow deny  
  `order`, defines if the deny or allow control shall be performed first.  
  If the order is set to allow deny, then first the users network address is controlled to be in the allow subset. If the users network address is not in the allowed subset he will be denied to get the asset. If the network-address is in the allowed subset then a second control will be performed, that the users network address is not in the subset of network addresses that shall be denied as specified by the deny parameter.  
  If the order is set to deny allow then only users from networks specified to be in the allowed subset will succeed to request assets in the limited area.

- **DIRECTIVE:** “require”  
  Syntax: `require group group1 group2... | user user1 user2...`  
  Default: - None -  
  Context: Limit  
  See the require directive in the documentation of mod_auth(3) for more information.

### 1.4.7 Dynamic Web Pages

The Inets HTTP server provides two ways of creating dynamic web pages, each with its own advantages and disadvantages.

First there are CGI-scripts that can be written in any programming language. CGI-scripts are standardized and supported by most webservers. The drawback with CGI-scripts is that they are resource intensive because of their design. CGI requires the server to fork a new OS process for each executables it needs to start.

Second there are ESI-functions that provide a tight and efficient interface to the execution of Erlang functions, this interface on the other hand is Inets specific.

The Common Gateway Interface (CGI) Version 1.1, RFC 3875.

The mod_cgi module makes it possible to execute CGI scripts in the server. A file that matches the definition of a ScriptAlias config directive is treated as a CGI script. A CGI script is executed by the server and it’s output is returned to the client.

The CGI Script response comprises a message-header and a message-body, separated by a blank line. The message-header contains one or more header fields. The body may be empty. Example:
"Content-Type:text/plain\nAccept-Ranges:none\n
some very plain text"

The server will interpret the cgi-headers and most of them will be transformed into HTTP headers and sent back to the client together with the body.
Support for CGI-1.1 is implemented in accordance with the RFC 3875.

Erlang Server Interface (ESI)
The erlang server interface is implemented by the module mod_esi.

ERL Scheme  The erl scheme is designed to mimic plain CGI, but without the extra overhead. An URL which calls an Erlang erl function has the following syntax (regular expression):

http://your.server.org/***/Module[/]Function(?QueryString|/PathInfo)

*** above depends on how the ErlScriptAlias config directive has been used
The module (Module) referred to must be found in the code path, and it must define a function (Function) with an arity of two or three. It is preferable to implement a function with arity three as it permits you to send chunks of the webpage being generated to the client during the generation phase instead of first generating the whole web page and then sending it to the client. The option to implement a function with arity two is only kept for backwardcompatibility reasons. See mod_esi(3) [page 76] for implementation details of the esi callback function.

EVAL Scheme  The eval scheme is straight-forward and does not mimic the behavior of plain CGI. An URL which calls an Erlang eval function has the following syntax:

http://your.server.org/***/Mod:Func(Arg1,...,ArgN)

*** above depends on how the ErlScriptAlias config directive has been used
The module (Mod) referred to must be found in the code path, and data returned by the function (Func) is passed back to the client. Data returned from the function must furthermore take the form as specified in the CGI specification. See mod_esi(3) [page 76] for implementation details of the esi callback function.

Note:
The eval scheme can seriously threaten the integrity of the Erlang node housing a Web server, for example:

http://your.server.org/eval?httpd_example:print(atom_to_list(apply(erlang,halt,[])))

which effectively will close down the Erlang node, that is use the erl scheme instead, until this security breach has been fixed.
Today there are no good way of solving this problem and therefore Eval Scheme may be removed in future release of Inets.
1.4.8 Logging

There are three types of logs supported. Transfer logs, security logs and error logs. The de-facto standard Common Logfile Format is used for the transfer and security logging. There are numerous statistics programs available to analyze Common Logfile Format. The Common Logfile Format looks as follows:

```
remotehost rfc931 authuser [date] “request” status bytes
```

- **remotehost**: Remote hostname
- **rfc931**: The client's remote username (RFC 931).
- **authuser**: The username with which the user authenticated himself.
- **[date]**: Date and time of the request (RFC 1123).
- **“request”**: The request line exactly as it came from the client (RFC 1945).
- **status**: The HTTP status code returned to the client (RFC 1945).
- **bytes**: The content-length of the document transferred.

Internal server errors are recorded in the error log file. The format of this file is a more ad hoc format than the logs using Common Logfile Format, but conforms to the following syntax:

```
[date] access to path failed for remotehost, reason: reason
```

1.4.9 Server Side Includes

Server Side Includes enables the server to run code embedded in HTML pages to generate the response to the client.

**Note:**

Having the server parse HTML pages is a double-edged sword! It can be costly for a heavily loaded server to perform parsing of HTML pages while sending them. Furthermore, it can be considered a security risk to have average users executing commands in the name of the Erlang node user. Carefully consider these items before activating server-side includes.

**SERVER-SIDE INCLUDES (SSI) SETUP**

The server must be told which filename extensions to be used for the parsed files. These files, while very similar to HTML, are not HTML and are thus not treated the same. Internally, the server uses the magic MIME type **text/x-server-parsed-html** to identify parsed documents. It will then perform a format conversion to change these files into HTML for the client. Update the **mime.types** file, as described in the Mime Type Settings, to tell the server which extension to use for parsed files, for example:

```
text/x-server-parsed-html shtml shtm
```

This makes files ending with .shtml and .shtm into parsed files. Alternatively, if the performance hit is not a problem, all HTML pages can be marked as parsed:

```
text/x-server-parsed-html html htm
```
Server-Side Includes (SSI) Format

All server-side include directives to the server are formatted as SGML comments within the HTML page. This is in case the document should ever find itself in the client's hands unparsed. Each directive has the following format:

\[
<!--\#command tag1=\"value1\" tag2=\"value2\" -->
\]

Each command takes different arguments, most only accept one tag at a time. Here is a breakdown of the commands and their associated tags:

**config**  The config directive controls various aspects of the file parsing. There are two valid tags:

- **errmsg** controls the message sent back to the client if an error occurred while parsing the document. All errors are logged in the server's error log.
- **sizefmt** determines the format used to display the size of a file. Valid choices are *bytes* or *abbrev*. *bytes* for a formatted byte count or *abbrev* for an abbreviated version displaying the number of kilobytes.

**include** will insert the text of a document into the parsed document. This command accepts two tags:

- **virtual** gives a virtual path to a document on the server. Only normal files and other parsed documents can be accessed in this way.
- **file** gives a pathname relative to the current directory. ../ cannot be used in this pathname, nor can absolute paths. As above, you can send other parsed documents, but you cannot send CGI scripts.

**echo** prints the value of one of the include variables (defined below). The only valid tag to this command is **var**, whose value is the name of the variable you wish to echo.

**fsize** prints the size of the specified file. Valid tags are the same as with the **include** command. The resulting format of this command is subject to the **sizefmt** parameter to the **config** command.

**flastmod** prints the last modification date of the specified file. Valid tags are the same as with the **include** command.

**exec** executes a given shell command or CGI script. Valid tags are:

- **cmd** executes the given string using /bin/sh. All of the variables defined below are defined, and can be used in the command.
- **cgi** executes the given virtual path to a CGI script and includes its output. The server does not perform error checking on the script output.

Server-Side Includes (SSI) Environment Variables

A number of variables are made available to parsed documents. In addition to the CGI variable set, the following variables are made available:

**DOCUMENT_NAME**  The current filename.

**DOCUMENT_URI**  The virtual path to this document (such as /docs/tutorials/foo.shtml).

**QUERY_STRING**  The unescaped version of any search query the client sent, with all shell-special characters escaped with \\.

**DATE_LOCAL**  The current date, local time zone.

**DATE_GMT**  Same as **DATE_LOCAL** but in Greenwich mean time.

**LAST_MODIFIED**  The last modification date of the current document.
1.4.10 The Erlang Webserver API

The process of handling a HTTP request involves several steps such as:

- Setting up connections, sending and receiving data.
- URI to filename translation
- Authentication/access checks.
- Retrieving/generating the response.
- Logging

To provide customization and extensibility of the HTTP servers request handling most of these steps are handled by one or more modules that may be replaced or removed at runtime, and of course new ones can be added. For each request all modules will be traversed in the order specified by the modules directive in the server configuration file. Some parts mainly the communication related steps are considered server core functionality and are not implemented using the Erlang Webserver API. A description of functionality implemented by the Erlang Webserver API is described in the section Inets Webserver Modules.

A module can use data generated by previous modules in the Erlang Webserver API module sequence or generate data to be used by consecutive Erlang Webserver API modules. This is made possible due to an internal list of key-value tuples, also referred to as interaction data.

**Note:**
Interaction data enforces module dependencies and should be avoided if possible. This means the order of modules in the Modules config directive is significant.

**API Description**

Each module implements server functionality using the Erlang Webserver API should implement the following callback functions:

- do/1 (mandatory) - the function called when a request should be handled.
- load/2
- store/2
- remove/1

The latter functions are needed only when new config directives are to be introduced. For details see httpd(3) [page 54]

1.4.11 Inets Webserver Modules

The convention is that all modules implementing some webserver functionality has the name mod_*.

When configuring the webserver an appropriate selection of these modules should be present in the Module directive. Please note that there are some interaction dependencies to take into account so the order of the modules can not be totally random.
mod_action - Filetype/Method-Based Script Execution.

Runs CGI scripts whenever a file of a certain type or HTTP method (See RFC 1945) is requested.

Uses the following Erlang Webserver API interaction data, if available:
- real_name - from mod_alias

Exports the following Erlang Webserver API interaction data, if possible:
{new_request_uri, RequestURI}  An alternative RequestURI has been generated.

mod_alias - URL Aliasing

This module makes it possible to map different parts of the host file system into the document tree e.i. creates aliases and redirections.

Exports the following Erlang Webserver API interaction data, if possible:
{real_name, PathData}  PathData is the argument used for API function mod_alias:path/3.

mod_auth - User Authentication

This module provides for basic user authentication using textual files, dets databases as well as mnesia databases.

Uses the following Erlang Webserver API interaction data, if available:
- real_name - from mod_alias

Exports the following Erlang Webserver API interaction data, if possible:
{remote_user, User}  The user name with which the user has authenticated himself.

mod cgi - CGI Scripts

This module handles invoking of CGI scripts

mod_dir - Directories

This module generates an HTML directory listing (Apache-style) if a client sends a request for a directory instead of a file. This module needs to be removed from the Modules config directive if directory listings is unwanted.

Uses the following Erlang Webserver API interaction data, if available:
- real_name - from mod_alias

Exports the following Erlang Webserver API interaction data, if possible:
{mime_type, MimeType}  The file suffix of the incoming URL mapped into a MimeType.
mod_disk_log - Logging Using disk_log.

Standard logging using the “Common Logfile Format” and disk_log(3).
Uses the following Erlang Webserver API interaction data, if available:

- remote_user - from mod_auth

mod_esi - Erlang Server Interface

This module implements the Erlang Server Interface (ESI) that provides a tight and efficient interface
to the execution of Erlang functions.
Uses the following Erlang Webserver API interaction data, if available:

- remote_user - from mod_auth

Exports the following Erlang Webserver API interaction data, if possible:

{mime_type, MimeType}  The file suffix of the incoming URL mapped into a MimeType

mod_get - Regular GET Requests

This module is responsible for handling GET requests to regular files. GET requests for parts of files is
handled by mod_range.
Uses the following Erlang Webserver API interaction data, if available:

- real_name - from mod_alias

mod_head - Regular HEAD Requests

This module is responsible for handling HEAD requests to regular files. HEAD requests for dynamic
content is handled by each module responsible for dynamic content.
Uses the following Erlang Webserver API interaction data, if available:

- real_name - from mod_alias

mod_htaccess - User Configurable Access

This module provides per-directory user configurable access control.
Uses the following Erlang Webserver API interaction data, if available:

- real_name - from mod_alias

Exports the following Erlang Webserver API interaction data, if possible:

{remote_user_name, User}  The user name with which the user has authenticated himself.
mod\_include - SSI

This module makes it possible to expand “macros” embedded in HTML pages before they are delivered to the client, that is Server-Side Includes (SSI).

Uses the following Erlang Webserver API interaction data, if available:

- real\_name - from mod\_alias
- remote\_user - from mod\_auth

Exports the following Erlang Webserver API interaction data, if possible:

\{mime\_type, MimeType\}  The file suffix of the incoming URL mapped into a Mime\_Type as defined in the Mime Type Settings section.

mod\_log - Logging Using Text Files.

Standard logging using the “Common Logfile Format” and text files.

Uses the following Erlang Webserver API interaction data, if available:

- remote\_user - from mod\_auth

mod\_range - Requests with Range Headers

This module response to requests for one or many ranges of a file. This is especially useful when downloading large files, since a broken download may be resumed.

Note that request for multiple parts of a document will report a size of zero to the log file.

Uses the following Erlang Webserver API interaction data, if available:

- real\_name - from mod\_alias

mod\_response\_control - Requests with If* Headers

This module controls that the conditions in the requests is fullfilled. For example a request may specify that the answer only is of interest if the content is unchanged since last retrieval. Or if the content is changed the range-request shall be converted to a request for the whole file instead.

If a client sends more then one of the header fields that restricts the servers right to respond, the standard does not specify how this shall be handled. httpd will control each field in the following order and if one of the fields not match the current state the request will be rejected with a proper response.

1. If-modified
2. If-Unmodified
3. If-Match
4. If-Notmatch

Uses the following Erlang Webserver API interaction data, if available:

- real\_name - from mod\_alias

Exports the following Erlang Webserver API interaction data, if possible:

\{if\_range, send\_file\}  The conditions for the range request was not fullfilled. The response must not be treated as a range request, instead it must be treated as a ordinary get request.
mod_security - Security Filter

This module serves as a filter for authenticated requests handled in mod_auth. It provides possibility to restrict users from access for a specified amount of time if they fail to authenticate several times. It logs failed authentication as well as blocking of users, and it also calls a configurable call-back module when the events occur.

There is also an API to manually block, unblock and list blocked users or users, who have been authenticated within a configurable amount of time.

mod_trace - TRACE Request

mod_trace is responsible for handling of TRACE requests. Trace is a new request method in HTTP/1.1. The intended use of trace requests is for testing. The body of the trace response is the request message that the responding Web server or proxy received.
Inets Reference Manual

Short Summaries

- Erlang Module **ftp** [page 39] – A File Transfer Protocol client
- Erlang Module **http** [page 49] – An HTTP/1.1 client
- Erlang Module **http_base.64** [page 53] – Implements base 64 encode and decode, see RFC 2045.
- Erlang Module **httpd** [page 54] – An implementation of an HTTP 1.1 compliant Web server, as defined in RFC 2616.
- Erlang Module **httpd_conf** [page 60] – Configuration utility functions to be used by the Erlang Webserver API programmer.
- Erlang Module **httpd_socket** [page 62] – Communication utility functions to be used by the Erlang Webserver API programmer.
- Erlang Module **httpd_util** [page 63] – Miscellaneous utility functions to be used when implementing Erlang Webserver API modules.
- Erlang Module **mod_alias** [page 69] – URL aliasing.
- Erlang Module **mod_auth** [page 71] – User authentication using text files, dets or mnesia database.
- Erlang Module **mod_esi** [page 76] – Erlang Server Interface
- Erlang Module **mod_security** [page 78] – Security Audit and Trailing Functionality

**ftp**

The following functions are exported:

- `account(Pid, Account) -> ok | {error, Reason}`
  [page 40] Specify which account to use.
- `append(Pid, LocalFile [, RemoteFile]) -> ok | {error, Reason}`
  [page 40] Transfer file to remote server, and append it to Remotefile.
- `append_bin(Pid, Bin, RemoteFile) -> ok | {error, Reason}`
  [page 40] Transfer a binary into a remote file.
- `append_chunk(Pid, Bin) -> ok | {error, Reason}`
  [page 40] Append a chunk to the remote file.
- `append_chunk_start(Pid, File) -> ok | {error, Reason}`
  [page 40] Start transfer of file chunks for appending to File.
- `append_chunk_end(Pid) -> ok | {error, Reason}`
  [page 41] Stop transfer of chunks for appending.
- `cd(Pid, Dir) -> ok | {error, Reason}`  
  [page 41] Change remote working directory.

- `close(Pid) -> ok`  
  [page 41] End ftp session.

- `delete(Pid, File) -> ok | {error, Reason}`  
  [page 41] Delete a file at the remote server.

- `formaterror(Tag) -> string()`  
  [page 41] Return error diagnostics.

- `lcd(Pid, Dir) -> ok | {error, Reason}`  
  [page 41] Change local working directory.

- `lpwd(Pid) -> ok, Dir`  
  [page 41] Get local current working directory.

- `ls(Pid [, Dir]) -> {ok, Listing} | {error, Reason}`  
  [page 42] List contents of remote directory.

- `mkdir(Pid, Dir) -> ok | {error, Reason}`  
  [page 42] Create remote directory.

- `nlist(Pid [, Dir]) -> {ok, Listing} | {error, Reason}`  
  [page 42] List contents of remote directory.

- `open(Host [, Port] [, Flags]) -> {ok, Pid} | {error, Reason}`  

- `pwd(Pid) -> {ok, Dir} | {error, Reason}`  
  [page 44] Get remote current working directory.

- `recv(Pid, RemoteFile [, LocalFile]) -> ok | {error, Reason}`  
  [page 44] Transfer file from remote server.

- `recv_bin(Pid, RemoteFile) -> {ok, Bin} | {error, Reason}`  
  [page 44] Transfer file from remote server as a binary.

- `rename(Pid, Old, New) -> ok | {error, Reason}`  
  [page 45] Rename a file at the remote server.

- `rmdir(Pid, Dir) -> ok | {error, Reason}`  
  [page 45] Remove a remote directory.

- `send(Pid, LocalFile [, RemoteFile]) -> ok | {error, Reason}`  
  [page 45] Transfer file to remote server.

- `send_bin(Pid, Bin, RemoteFile) -> ok | {error, Reason}`  
  [page 46] Transfer a binary into a remote file.

- `rename(Pid, Old, New) -> ok | {error, Reason}`  
  [page 45] Rename a file at the remote server.

- `send_chunk_start(Pid, File) -> ok | {error, Reason}`  
  [page 46] Start transfer of file chunks.

- `send_chunk_end(Pid) -> ok | {error, Reason}`  
  [page 46] Stop transfer of chunks.
- \texttt{type(Pid, Type) -> ok | \{error, Reason\}}
  [page 46] Set transfer type to ascii or binary.

- \texttt{user(Pid, User, Password) -> ok | \{error, Reason\}}
  [page 46] User login.

- \texttt{user(Pid, User, Password, Account) -> ok | \{error, Reason\}}
  [page 47] User login.

- \texttt{quote(Pid, Command) -> [FTPLine]}
  [page 47] Sends an arbitrary FTP command.

\section*{http}

The following functions are exported:

- \texttt{cancel_request(RequestId) -> ok}
  [page 50] Cancels an asynchronous HTTP-request.

- \texttt{request(Url) -> \{ok, Result\} | \{error, Reason\}}
  [page 50] Sends a get HTTP-request.

- \texttt{request(Method, Request, HTTPOptions, Options) -> \{ok, Result\} | \{error, Reason\}}
  [page 50] Sends a HTTP-request.

- \texttt{set_options(Options) -> ok}
  [page 51] Sets options to be used for subsequent requests.

- \texttt{verify_cookie(SetCookieHeaders, Url) -> ok}
  [page 52] Saves the cookies defined in SetCookieHeaders in the client manager's cookie database.

- \texttt{cookie_header(Url) -> header()}
  [page 52] Returns the cookie header that would be sent when making a request to Url.

\section*{http_base_64}

The following functions are exported:

- \texttt{encode(PlainASCII) -> Base64}
  [page 53] Encodes a plain ASCII string into base64.

- \texttt{decode(Base64) -> PlainASCII}
  [page 53] Decodes an base64 encoded string to plain ASCII.

\section*{httpd}

The following functions are exported:

- \texttt{Module:do(ModData) -> \{proceed, OldData\} | \{proceed, NewData\} | \{break, NewData\} | done}
  [page 55] Called for each request to the Web server.

- \texttt{Module:load(Line, Context) -> eof | ok | \{ok, NewContext\} | \{ok, NewContext, Directive\} | \{ok, NewContext, DirectiveList\} | \{error, Reason\}}
  [page 56] Load a configuration directive.
  [page 56] Alter the value of one or more configuration directive.
- Module:remove(ConfigDB) -> ok | {error, Reason}
  [page 56] Callback function that is called when the Web server is closed.
- parse_query(QueryString) -> ServerRet
  [page 57] Parse incoming data to erl and eval scripts
- start() [page 57] Start a server as specified in the given config file.
- start(Config) -> ServerRet
  [page 57] Start a server as specified in the given config file.
- start_link() [page 57] Start a server as specified in the given config file.
- start_link(Config) -> ServerRet
  [page 57] Start a server as specified in the given config file.
- restart() [page 58] Restart a running server.
- restart(Port) -> ok | {error,Reason}
  [page 58] Restart a running server.
- restart(ConfigFile) -> ok | {error,Reason}
  [page 58] Restart a running server.
- restart(Address,Port) -> ok | {error,Reason}
  [page 58] Restart a running server.
- stop() [page 58] Stop a running server.
- stop(Port) -> ServerRet
  [page 58] Stop a running server.
- stop(ConfigFile) -> ServerRet
  [page 58] Stop a running server.
- stop(Address,Port) -> ServerRet
  [page 58] Stop a running server.
- block() -> ok | {error,Reason}
  [page 58] Block a running server.
- block(Port) -> ok | {error,Reason}
  [page 58] Block a running server.
- block(ConfigFile) -> ok | {error,Reason}
  [page 58] Block a running server.
- block(Address,Port) -> ok | {error,Reason}
  [page 58] Block a running server.
block(ConfigFile,Mode,Timeout) -> ok | {error,Reason}
[page 58] Block a running server.

block(Address,Port,Mode,Timeout) -> ok | {error,Reason}
[page 58] Block a running server.

unblock() -> ok | {error,Reason}
[page 59] Unblock a blocked server.

unblock(Port) -> ok | {error,Reason}
[page 59] Unblock a blocked server.

unblock(ConfigFile) -> ok | {error,Reason}
[page 59] Unblock a blocked server.

unblock(Address,Port) -> ok | {error,Reason}
[page 59] Unblock a blocked server.

httpd_conf
The following functions are exported:

- check_enum(EnumString,ValidEnumStrings) -> Result
  [page 60] Check if string is a valid enumeration.

- clean(String) -> Stripped
  [page 60] Remove leading and/or trailing white spaces.

- custom_clean(String,Before,After) -> Stripped
  [page 60] Remove leading and/or trailing white spaces and custom characters.

- is_directory(FilePath) -> Result
  [page 60] Check if a file path is a directory.

- is_file(FilePath) -> Result
  [page 61] Check if a file path is a regular file.

- make_integer(String) -> Result
  [page 61] Return an integer representation of a string.

httpd_socket
The following functions are exported:

- deliver(SocketType,Socket,Data) -> Result
  [page 62] Send binary data over socket.

- peername(SocketType,Socket) -> {Port,IPAddress}
  [page 62] Return the port and IP-address of the remote socket.

- resolve() -> HostName
  [page 62] Return the official name of the current host.
httpd_util

The following functions are exported:

- `convert_request_date(DateString) -> ErlDate|bad_date`
  - [page 63] Convert the date to the Erlang date format.
- `create_etag(FileInfo) -> Etag`
  - [page 63] Calculates the Etag for a file.
- `decode_base64(Base64String) -> ASCIIString`
  - [page 63] Convert a base64 encoded string to a plain ascii string.
- `decode_hex(HexValue) -> DecValue`
  - [page 63] Convert a hex value into its decimal equivalent.
- `day(NthDayOfWeek) -> DayOfWeek`
  - [page 63] Convert the day of the week (integer [1-7]) to an abbreviated string.
- `encode_base64(ASCIIString) -> Base64String`
  - [page 64] Convert an ASCII string to a Base64 encoded string.
- `flatlength(NestedList) -> Size`
  - [page 64] Compute the size of a possibly nested list.
- `header(StatusCode,PersistentConn)`
  - [page 64] Generate a HTTP 1.1 header.
- `header(StatusCode,Date)`
  - [page 64] Generate a HTTP 1.1 header.
- `header(StatusCode,MimeType,Date)`
  - [page 64] Generate a HTTP 1.1 header.
- `header(StatusCode,MimeType,PersistentConn,Date) -> HTTPHeader`
  - [page 64] Generate a HTTP 1.1 header.
- `hexlist_to_integer(HexString) -> Number`
  - [page 64] Convert a hexadecimal string to an integer.
- `integer_tohexlist(Number) -> HexString`
  - [page 64] Convert an integer to a hexadecimal string.
- `key1search(TupleList,Key)`
  - [page 65] Search a list of key-value tuples for a tuple whose first element is a key.
- `key1search(TupleList,Key,Undefined) -> Result`  
  - [page 65] Search a list of key-value tuples for a tuple whose first element is a key.
- `lookup(ETSTable,Key) -> Result`  
  - [page 65] Extract the first value associated with a key in an ETS table.
- `lookup(ETSTable,Key,Undefined) -> Result`  
  - [page 65] Extract the first value associated with a key in an ETS table.
- `lookup_mime(ConfigDB,Suffix)`  
  - [page 65] Return the mime type associated with a specific file suffix.
- `lookup_mime(ConfigDB,Suffix,Undefined) -> MimeType`  
  - [page 65] Return the mime type associated with a specific file suffix.
- `lookup_mime_default(ConfigDB,Suffix)`  
  - [page 65] Return the mime type associated with a specific file suffix or the value of the DefaultType.
- `lookup_mime_default(ConfigDB,Suffix,Undefined) -> MimeType`  
  - [page 65] Return the mime type associated with a specific file suffix or the value of the DefaultType.
- `message(StatusCode,PhraseArgs,ConfigDB) -> Message`
  [page 66] Return an informative HTTP 1.1 status string in HTML.

- `month(NthMonth) -> Month`
  [page 66] Convert the month as an integer (1-12) to an abbreviated string.

- `multi_lookup(ETSTable,Key) -> Result`
  [page 66] Extract the values associated with a key in an ETS table.

- `reason_phrase(StatusCode) -> Description`
  [page 66] Return the description of an HTTP 1.1 status code.

- `rfc1123_date() -> RFC1123Date`
  [page 67] Return the current date in RFC 1123 format.

- `rfc1123_date([YYYY,MM,DD],[Hour,Min,Sec]]) -> RFC1123Date`
  [page 67] Return the current date in RFC 1123 format.

- `split(String,RegExp,N) -> SplitRes`
  [page 67] Split a string in N chunks using a regular expression.

- `split_script_path(RequestLine) -> Splitted`
  [page 67] Split a RequestLine in a file reference to an executable and a QueryString or a PathInfo String.

- `split_path(RequestLine) -> {Path,QueryStringOrPathInfo}`
  [page 67] Split a RequestLine in a file reference and a QueryString or a PathInfo String.

- `strip(String) -> Stripped`
  [page 67] Returns String where the leading and trailing space and tabs has been removed.

- `suffix(FileName) -> Suffix`
  [page 68] Extract the file suffix from a given filename.

- `to_lower(String) -> ConvertedString`
  [page 68] Convert upper-case letters to lower-case.

- `to_upper(String) -> ConvertedString`
  [page 68] Convert lower-case letters to upper-case.

### mod_alias

The following functions are exported:

- `default_index(ConfigDB, Path) -> NewPath`
  [page 69] Return a new path with the default resource or file appended.

- `path(PathData, ConfigDB, RequestURI) -> Path`
  [page 69] Return the actual file path to a URL.

- `real_name(ConfigDB, RequestURI, Aliases) -> Ret`
  [page 69] Expand a request uri using Alias config directives.

- `real_script_name(ConfigDB, RequestURI, ScriptAliases) -> Ret`
  [page 70] Expand a request uri using Script Alias config directives.
mod_auth

The following functions are exported:

- `add_user(UserName, Options) -> true | {error, Reason}`
  [page 71] Add a user to the user database.
- `add_user(UserName, Password, UserData, Port, Dir) -> true | {error, Reason}`
  [page 71] Add a user to the user database.
- `add_user(UserName, Password, UserData, Address, Port, Dir) -> true | {error, Reason}`
  [page 71] Add a user to the user database.
- `delete_user(UserName, Options) -> true | {error, Reason}`
  [page 71] Delete a user from the user database.
- `delete_user(UserName, Port, Dir) -> true | {error, Reason}`
  [page 71] Delete a user from the user database.
- `delete_user(UserName, Address, Port, Dir) -> true | {error, Reason}`
  [page 71] Delete a user from the user database.
- `get_user(UserName, Options) -> {ok, #httpd_user} | {error, Reason}`
  [page 72] Returns a user from the user database.
- `get_user(UserName, Port, Dir) -> {ok, #httpd_user} | {error, Reason}`
  [page 72] Returns a user from the user database.
- `get_user(UserName, Address, Port, Dir) -> {ok, #httpd_user} | {error, Reason}`
  [page 72] Returns a user from the user database.
- `list_users(Options) -> {ok, Users} | {error, Reason}`
  [page 72] List users in the user database.
- `list_users(Port, Dir) -> {ok, Users} | {error, Reason}`
  [page 72] List users in the user database.
- `add_group_member(GroupName, UserName, Options) -> true | {error, Reason}`
  [page 72] Add a user to a group.
- `add_group_member(GroupName, UserName, Port, Dir) -> true | {error, Reason}`
  [page 72] Add a user to a group.
- `add_group_member(GroupName, UserName, Address, Port, Dir) -> true | {error, Reason}`
  [page 72] Add a user to a group.
- `delete_group_member(GroupName, UserName, Options) -> true | {error, Reason}`
  [page 73] Remove a user from a group.
- `delete_group_member(GroupName, UserName, Port, Dir) -> true | {error, Reason}`
  [page 73] Remove a user from a group.
- `delete_group_member(GroupName, UserName, Address, Port, Dir) -> true | {error, Reason}`
  [page 73] Remove a user from a group.
Inets Reference Manual

- `list_group_members(GroupName, Options) -> {ok, Users} | {error, Reason}`
  [page 73] List the members of a group.
- `list_group_members(GroupName, Port, Dir) -> {ok, Users} | {error, Reason}`
  [page 73] List the members of a group.
- `list_group_members(GroupName, Address, Port, Dir) -> {ok, Users} | {error, Reason}`
  [page 73] List the members of a group.
- `list_groups(Options) -> {ok, Groups} | {error, Reason}`
  [page 74] List all the groups.
- `list_groups(Port, Dir) -> {ok, Groups} | {error, Reason}`
  [page 74] List all the groups.
- `list_groups(Address, Port, Dir) -> {ok, Groups} | {error, Reason}`
  [page 74] List all the groups.
- `delete_group(GroupName, Options) -> true | {error, Reason}`
  [page 74] Deletes a group.
- `<name>delete_group(GroupName, Port, Dir) -> true | {error, Reason}`
  [page 74] Deletes a group.
- `delete_group(GroupName, Address, Port, Dir) -> true | {error, Reason}`
  [page 74] Deletes a group.
- `update_password(Port, Dir, OldPassword, NewPassword, NewPassword) -> ok | {error, Reason}`
  [page 74] Change the AuthAccessPassword.
- `update_password(Address, Port, Dir, OldPassword, NewPassword, NewPassword) -> ok | {error, Reason}`
  [page 74] Change the AuthAccessPassword.

**mod_esi**

The following functions are exported:

- `deliver(SessionID, Data) -> ok | {error, Reason}`
  [page 76] Sends Data back to client.
- `Module:Function(SessionID, Env, Input) -> _`  
  [page 76] Creates a dynamic web page and returns it chunk by chunk to the server process by calling `mod_esi:deliver/2`.
- `Module:Function(Env, Input) -> Response`  
  [page 77] Creates a dynamic web page and return it as a list. This functions is deprecated and only kept for backwards compatibility.

**mod_security**

The following functions are exported:

- `list_auth_users(Port) -> Users | []`
  [page 78] List users that have authenticated within the SecurityAuthTimeout time for a given address (if specified), port number and directory (if specified).
• `list_auth_users(Address, Port) -> Users | []`
  [page 78] List users that have authenticated within the SecurityAuthTimeout time for a given address (if specified), port number and directory (if specified).

• `list_auth_users(Port, Dir) -> Users | []`
  [page 78] List users that have authenticated within the SecurityAuthTimeout time for a given address (if specified), port number and directory (if specified).

• `list_auth_users(Address, Port, Dir) -> Users | []`
  [page 78] List users that have authenticated within the SecurityAuthTimeout time for a given address (if specified), port number and directory (if specified).

• `list_blocked_users(Port) -> Users | []`
  [page 78] List users that are currently blocked from access to a specified port number, for a given address (if specified).

• `list_blocked_users(Address, Port) -> Users | []`
  [page 78] List users that are currently blocked from access to a specified port number, for a given address (if specified).

• `list_blocked_users(Port, Dir) -> Users | []`
  [page 78] List users that are currently blocked from access to a specified port number, for a given address (if specified).

• `list_blocked_users(Address, Port, Dir) -> Users | []`
  [page 78] List users that are currently blocked from access to a specified port number, for a given address (if specified).

• `block_user(User, Port, Dir, Seconds) -> true | {error, Reason}`
  [page 78] Block user from access to a directory for a certain amount of time.

• `block_user(User, Address, Port, Dir, Seconds) -> true | {error, Reason}`
  [page 78] Block user from access to a directory for a certain amount of time.

• `unblock_user(User, Port) -> true | {error, Reason}`
  [page 79] Remove a blocked user from the block list

• `unblock_user(User, Address, Port) -> true | {error, Reason}`
  [page 79] Remove a blocked user from the block list

• `unblock_user(User, Port, Dir) -> true | {error, Reason}`
  [page 79] Remove a blocked user from the block list

• `unblock_user(User, Address, Port, Dir) -> true | {error, Reason}`
  [page 79] Remove a blocked user from the block list

• `event(What, Port, Dir, Data) -> ignored`
  [page 79] This function is called whenever an event occurs in mod_security

• `event(What, Address, Port, Dir, Data) -> ignored`
  [page 79] This function is called whenever an event occurs in mod_security
The `ftp` module implements a client for file transfer according to a subset of the File Transfer Protocol (see RFC 959). Starting from inets version 4.4.1 the ftp client will always try to use passive ftp mode and only resort to active ftp mode if this fails. There is a mode option for open/[1,2,3] where this default behavior may be changed. Also the mode option replaces the API function `force_active/1` that now has become deprecated. (`force_active/1` is removed from the documentation but is still available in the code for now.)

For a simple example of an ftp session see Inets User's Guide. [page 2]

In addition to the ordinary functions for receiving and sending files (see `recv/2`, `recv/3`, `send/2` and `send/3`) there are functions for receiving remote files as binaries (see `recv/2`) and for sending binaries to to be stored as remote files (see `send/2`).

There is also a set of functions for sending and receiving contiguous parts of a file to be stored in a remote file (for send see `send_chunk_start/2`, `send_chunk/2` and `send_chunk_end/1` and for receive see `recv_chunk_start/2` and `recv_chunk/1`).

The particular return values of the functions below depend very much on the implementation of the FTP server at the remote host. In particular the results from `ls` and `nlist` varies. Often real errors are not reported as errors by `ls`, even if for instance a file or directory does not exist. `nlist` is usually more strict, but some implementations have the peculiar behaviour of responding with an error, if the request is a listing of the contents of directory which exists but is empty.

**COMMON DATA TYPES**

Here follows type definitions that are used by more than one function in the FTP client API.

- `pid()` - identifier of an ftp connection.
- `string()` = list of ASCII characters
- `shortage_reason()` = etnospc | epnospc
- `restriction_reason()` = epath | efnamen| elogin | enotbinary
  - note not all restrictions may always relevant to all functions
- `common_reason()` = econn | eclosed | term() - some kind of explanation of what went wrong
Exports

account(Pid, Account) - ok | {error, Reason}
Types:
- Pid = pid()
- Account = string()
- Reason = ecacct | common_reason()
If an account is needed for an operation set the account with this operation.

append(Pid, LocalFile [, RemoteFile]) - ok | {error, Reason}
Types:
- Pid = pid()
- LocalFile = RemoteFile = string()
- Reason = epath | elogin | etnospc | epnospc | efnamena | common_reason
Transfers the file LocalFile to the remote server. If RemoteFile is specified, the name of the remote file that the file will be appended to is set to RemoteFile; otherwise the name is set to LocalFile if the file does not exist it will be created.

append_bin(Pid, Bin, RemoteFile) - ok | {error, Reason}
Types:
- Pid = pid()
- Bin = binary()
- RemoteFile = string()
- Reason = restriction_reason() | shortage_reason() | common_reason()
Transfers the binary Bin to the remote server and append it to the file RemoteFile. If the file does not exist it will be created.

append_chunk(Pid, Bin) - ok | {error, Reason}
Types:
- Pid = pid()
- Bin = binary()
- Reason = echunk | restriction_reason() | common_reason()
Transfer the chunk Bin to the remote server, which append it into the file specified in the call to append_chunk_start/2.
Note that for some errors, e.g. file system full, it is necessary to call append_chunk_end to get the proper reason.

append_chunk_start(Pid, File) - ok | {error, Reason}
Types:
- Pid = pid()
- File = string()
- Reason = restriction_reason() | common_reason()
Start the transfer of chunks for appending to the file File at the remote server. If the file does not exist it will be created.

append_chunk_end(Pid) -> ok | {error, Reason}
Types:
- Pid = pid()
- Reason = echunk | restriction_reason() | shortage_reason()

Stops transfer of chunks for appending to the remote server. The file at the remote server, specified in the call to append_chunk_start/2 is closed by the server.

cd(Pid, Dir) -> ok | {error, Reason}
Types:
- Pid = pid()
- Dir = string()
- Reason = restriction_reason() | common_reason()
Changes the working directory at the remote server to Dir.

close(Pid) -> ok
Types:
- Pid = pid()
Ends the ftp session.

delete(Pid, File) -> ok | {error, Reason}
Types:
- Pid = pid()
- File = string()
- Reason = restriction_reason() | common_reason()
Deletes the file File at the remote server.

formaterror(Tag) -> string()
Types:
- Tag = {error, atom()} | atom()
Given an error return value {error, AtomReason}, this function returns a readable string describing the error.

lcd(Pid, Dir) -> ok | {error, Reason}
Types:
- Pid = pid()
- Dir = string()
- Reason = restriction_reason()
Changes the working directory to Dir for the local client.

lpwd(Pid) -> {ok, Dir}
Types:
- Pid = pid()

Returns the current working directory at the local client.

**ls(Pid [, Dir])** -> {ok, Listing} | {error, Reason}

Types:
- Pid = pid()
- Dir = string()
- Listing = string()
- Reason = restriction_reason() | common_reason()

Returns a listing of the contents of the remote current directory (`ls/1`) or the specified directory (`ls/2`). The format of Listing is operating system dependent (on UNIX it is typically produced from the output of the `ls -l` shell command).

**mkdir(Pid, Dir)** -> ok | {error, Reason}

Types:
- Pid = pid()
- Dir = string()
- Reason = restriction_reason() | common_reason()

Creates the directory `Dir` at the remote server.

**nlist(Pid [, Dir])** -> {ok, Listing} | {error, Reason}

Types:
- Pid = pid()
- Dir = string()
- Listing = string()
- Reason = restriction_reason() | common_reason()

Returns a listing of the contents of the remote current directory (`nlist/1`) or the specified directory (`nlist/2`). The format of Listing is a stream of file names, where each name is separated by `<CRLF>` or `<NL>`. Contrary to the `ls` function, the purpose of `nlist` is to make it possible for a program to automatically process file name information.

**open(Host [, Port] [, Flags])** -> {ok, Pid} | {error, Reason}

**open({option_list, Option_list})** -> {ok, Pid} | {error, Reason}

Types:
- Host = string() | ip_address()
- ip_address() = {byte(), byte(), byte(), byte()} | {byte(), byte(), byte(), byte(), byte(), byte(), byte(), byte()}
- byte() = 0 | 1 | ... | 255
- Port = integer()
- Flags = [Flag]
- Flag = verbose | debug | ip_v6_disabled
- Pid = pid()
Inets Reference Manual

- Reason = ehost
- Option_list = [Options]
- Options = (host, Host) | (port, Port) | (mode, Mode) | (flags, Flags) | (timeout, Timeout) | (progress, ProgressOption)
- Mode = active | passive
- Timeout = integer()
- ProgressOption = ignore | {CBM odule, CBF unction, InitProgress}
- CallBackM odule = atom()
- CallBackF unction = atom()
- InitProgress = term()

Opens a session with the ftp server at Host. The argument Host is either the name of the host, its IP address in dotted decimal notation (e.g. "150.236.14.136"), or a tuple of arity 4 (ipv4) or 8 (ipv6) (ex: [150, 236, 14, 136]).

If Port is supplied, a connection is attempted using this port number instead of the default (21).

Default value for Mode is passive.

If the atom verbose is included in Flags, response messages from the remote server will be written to standard output.

The progress option is intended to be used by applications that want create some type of progress report such as a progress bar in a GUI. The default value for the progress option is ignore i.e. the option is not used. When the progress option is specified the following will happen when ftp:send/[3,4] or ftp:recv/[3,4] are called.

- Before a file is transfered the following call will be made to indicate the start of the file transfer and how big the file is. The return value of the callback function should be a new value for the UserProgressTerm that will be used as input next time the callback function is called.
  
  `CBModule:CBFunction(InitProgress, File, {file_size, FileSize})`

- Every time a chunk of bytes is transfered the following call will be made:
  
  `CBModule:CBFunction(UserProgressTerm, File, {transfer_size, TransferSize})`

- At the end of the file the following call will be made to indicate the end of the transfer.
  
  `CBModule:CBFunction(UserProgressTerm, File, {transfer_size, 0})`

The callback function should be defined as

`CBModule:CBFunction(UserProgressTerm, File, Size) -> UserProgressTerm`

`CBModule = CBFunction = atom()`

`UserProgressTerm = term()`

`File = string()`

`Size = {transfer_size, integer()} | {file_size, integer()} | {file_size, unknown}`
A las for remote files it is not possible for ftp to determine the file size in a platform independent way. In this case the size will be unknown and it is left to the application to find out the size.

**Note:**
The callback is made by a middleman process, hence the file transfer will not be affected by the code in the progress callback function. If the callback should crash this will be detected by the ftp connection process that will print an info-report and then go one as if the progress option was set to ignore.

The file transfer type is set to the default of the FTP server when the session is opened. This is usually ASCII-mode.

The current local working directory (cf. `lwpd/1`) is set to the value reported by `file:get_cwd/1`. the wanted local directory.

The timeout value is default set to 60000 milliseconds.

The return value `Pid` is used as a reference to the newly created ftp client in all other functions, and they should be called by the process that created the connection. The ftp client process monitors the process that created it and will terminate if that process terminates.

\[
pwd(Pid) \rightarrow \{\text{ok, Dir}\} \mid \{\text{error, Reason}\}
\]

**Types:**
- `Pid = pid()`
- `Reason = restriction_reason() \mid \text{common_reason()}`

Returns the current working directory at the remote server.

\[
recv(Pid, RemoteFile [, LocalFile]) \rightarrow \text{ok} \mid \{\text{error, Reason}\}
\]

**Types:**
- `Pid = pid()`
- `RemoteFile = LocalFile = string()`
- `Reason = restriction_reason() \mid \text{common_reason() \mid file:write_error_reason()}`
- `file:write_error_reason() = \text{see file:write/2}`

Transfer the file `RemoteFile` from the remote server to the file system of the local client. If `LocalFile` is specified, the local file will be `LocalFile`; otherwise it will be `RemoteFile`.

If the file write fails (e.g. enospc), then the command is aborted and `\{\text{error, file:write_error_reason()}\}` is returned. The file is however not removed.

\[
recv\_bin(Pid, RemoteFile) \rightarrow \{\text{ok, Bin}\} \mid \{\text{error, Reason}\}
\]

**Types:**
- `Pid = pid()`
- `Bin = binary()`
- `RemoteFile = string()`
- `Reason = restriction_reason() \mid \text{common_reason()}`
Transfers the file RemoteFile from the remote server and receives it as a binary.

recv\_chunk\_start(Pid, RemoteFile) \rightarrow \text{ok} | \text{error, Reason}

Types:
- Pid = pid()
- RemoteFile = string()
- Reason = restriction\_reason() \& common\_reason()

Start transfer of the file RemoteFile from the remote server.

recv\_chunk(Pid) \rightarrow \text{ok} | \{\text{ok, Bin} \} | \{\text{error, Reason}\}

Types:
- Pid = pid()
- Bin = binary()
- Reason = restriction\_reason() \& common\_reason()

Receive a chunk of the remote file (RemoteFile of recv\_chunk\_start). The return values has the following meaning:

- \text{ok} the transfer is complete.
- \{\text{ok, Bin}\} just another chunk of the file.
- \{\text{error, Reason}\} transfer failed.

rename(Pid, Old, New) \rightarrow \text{ok} | \{\text{error, Reason}\}

Types:
- Pid = pid()
- CurrFile = NewFile = string()
- Reason = restriction\_reason() \& common\_reason()

Renames Old to New at the remote server.

rmdir(Pid, Dir) \rightarrow \text{ok} | \{\text{error, Reason}\}

Types:
- Pid = pid()
- Dir = string()
- Reason = restriction\_reason() \& common\_reason()

Removes directory Dir at the remote server.

send(Pid, LocalFile [, RemoteFile]) \rightarrow \text{ok} | \{\text{error, Reason}\}

Types:
- Pid = pid()
- LocalFile = RemoteFile = string()
- Reason = restriction\_reason() \& common\_reason() \& shortage\_reason()

Transfers the file LocalFile to the remote server. If RemoteFile is specified, the name of the remote file is set to RemoteFile; otherwise the name is set to LocalFile.
send_bin(Pid, Bin, RemoteFile) -> ok | {error, Reason}

Types:
- Pid = pid()
- Bin = binary()
- RemoteFile = string()
- Reason = restriction_reason() | common_reason() | shortage_reason()

Transfers the binary Bin into the file RemoteFile at the remote server.

send_chunk(Pid, Bin) -> ok | {error, Reason}

Types:
- Pid = pid()
- Bin = binary()
- Reason = echunk | restriction_reason() | common_reason()

Transfer the chunk Bin to the remote server, which writes it into the file specified in the call to send_chunk_start/2.

Note that for some errors, e.g. file system full, it is necessary to call send_chunk_end to get the proper reason.

send_chunk_start(Pid, File) -> ok | {error, Reason}

Types:
- Pid = pid()
- File = string()
- Reason = restriction_reason() | common_reason()

Start transfer of chunks into the file File at the remote server.

send_chunk_end(Pid) -> ok | {error, Reason}

Types:
- Pid = pid()
- Reason = restriction_reason() | common_reason() | shortage_reason()

Stops transfer of chunks to the remote server. The file at the remote server, specified in the call to send_chunk_start/2 is closed by the server.

type(Pid, Type) -> ok | {error, Reason}

Types:
- Pid = pid()
- Type = ascii | binary
- Reason = etype | restriction_reason() | common_reason()

Sets the file transfer type to ascii or binary. When an ftp session is opened, the transfer type is set to binary.

user(Pid, User, Password) -> ok | {error, Reason}

Types:
- Pid = pid()
user(Pid, User, Password, Account) -
ok | {error, Reason}

Types:
• Pid = pid()
• User = Password = string()
• Reason = euser | common_reason()
Performs login of User with Password to the account specified by Account.

quote(Pid, Command) -> [FTPLine]

Types:
• Pid = pid()
• Command = string()
• FTPLine = string() - Note the telnet end of line characters, from the ftp protocol
definition, CRLF e.g. "\r\n" has been removed.
Sends an arbitrary FTP command and returns verbatimly a list of the lines sent back by
the FTP server. This function is intended to give an application accesses to FTP
commands that are server specific or that may not be provided by this FTP client.

Note:
FTP commands that require a data connection can not be successfully issued with
this function.

ERRORS

The possible error reasons and the corresponding diagnostic strings returned by
formaterror/1 are as follows:

echunk  Synchronisation error during chunk sending.
   A call has been made to send_chunk/2 or send_chunk_end/1, before a call to
   send_chunk_start/2; or a call has been made to another transfer function during
   chunk sending, i.e. before a call to send_chunk_end/1.
eclosed The session has been closed.
econn  Connection to remote server prematurely closed.
ehost  Host not found, FTP server not found, or connection rejected by FTP server.
elogin User not logged in.
enoctbinary Term is not a binary.
epath No such file or directory, or directory already exists, or permission denied.
etype  No such type.
euser User name or password not valid.
enospc Insufficient storage space in system [452].
epnospc Exceeded storage allocation (for current directory or dataset) [552].
efnamea File name not allowed [553].

SEE ALSO

This module provides the API to a HTTP/1.1 client according to RFC 2616, however this early version is somewhat limited for instance caching is not supported.

**Note:**
The functions request/4, and set_options/1, will start the inets application if it was not already started. When starting the inets application the client manager process that spawns request handlers, keeps track of proxy options etc will be started. Normally the application using this API should have started inets application. This is also true for the ssl application when using https. 
Also note that an application that does not set the pipeline-timeout value will benefit very little from pipelining as the default timeout is 0.

There are some usage examples in the Inets User’s Guide. [page 2]

**COMMON DATA TYPES**

Type definitions that are used more than once in this module:

- **boolean()** = true | false
- **string()** = list of ASCII characters
- **request_id()** = ref()

**HTTP DATA TYPES**

Type definitions that are related to HTTP:
For more information about HTTP see rfc 2616

- **method()** = head | get | put | post | trace | options | delete
- **request()** - {url(), headers()} | {url(), headers(), content_type(), body()}
- **url()** = string() - Syntax according to the URI definition in rfc 2396, ex: "http://www.
- **status_line()** = {http_version(), status_code(), reason_phrase()}
- **http_version()** = string() ex: "HTTP/1.1"
- **status_code()** = integer()
reason_phrase() = string()
content_type() = string()
headers() = [{field(), value()}]
field() = string()
value() = string()
body() = string() | binary()

SSL DATA TYPES

Some type definitions relevant when using https, for details [ssl(3)]:

ssl_options() =
    {verify, code()} | {depth, depth()} | {certfile, path()}
    | {keyfile, path()} | {password, string()} | {cacertfile, path()}
    | {ciphers, string()}

Exports

cancel_request(RequestId) -> ok

Types:
• RequestId = request_id() - A unique identifier as returned by request/4
Cancels an asynchronous HTTP-request.

request(Url) -> {ok, Result} | {error, Reason}

Types:
• Url = url()
• Result = {status_line(), headers(), body()} | {status_code(), body()} | request_id()
• Reason = term()
Equivalent to http:request(get, {Url, []}, [], []).

request(Method, Request, HTTPOptions, Options) -> {ok, Result} | {error, Reason}

Types:
• Method = method()
• Request - request()
• HTTPOptions - [HttpOption]
• HTTPOption - {timeout, integer()} | {ssl, ssl_options()} | {autoredirect, boolean()}
  autoredirect - is true by default i.e. the client will automatically retrieve the
  information from the new URI and return that as the result instead of a 30X-result
  code. Note that for some 30X-result codes automatic redirect is not allowed in these
  cases the 30X-result will always be returned.
• Options - [option()]
• Option - {sync, boolean()} | {body_format, body_format()} | {full_result, boolean()}
The request function will be synchronous and return a full http response by default.
Inets Reference Manual

- body_format() = string() | binary()
  The body_format option is only valid for the synchronous request and the default is string. When making an asynchronous request the body will always be received as a binary.
- Result = {status_line(), headers(), body()} | {status_code(), body()} | request_id()
- Reason = term()

Sends a HTTP-request. The function can be both synchronous and asynchronous in the later case the function will return {ok, RequestId} and later on a message will be sent to the calling process on the format {http, {RequestId, Result}} or {http, {RequestId, {error, Reason}}}.

set_options(Options) -> ok

Types:
- Options = [Option]
- Option = {proxy, {Proxy, NoProxy}} | {max_sessions, MaxSessions} | {max_pipeline_length, MaxPipeline} | {pipeline_timeout, PipelineTimeout} | {cookies | CookieMode} | {ipv6, Ipv6Mode}
- Proxy = {Hostname, Port}
- Hostname = string()
  ex: "localhost" or "foo.bar.se"
- Port = integer()
  ex: 8080
- NoProxy = [NoProxyDesc]
  NoProxyDesc = DomainDesc | HostName | IPDesc
- DomainDesc = ".Domain"
  ex: ".ericsson.se"
- IPDesc = string()
  ex: "134.138" or ":FEDC:BA98" (all IP-addresses starting with 134.138 or FEDC:BA98), "66.35.250.150" or ":2010:836B:4179::836B:4179" (a complete IP-address).
- MaxSessions = integer()
  Maximum number of persistent connections to a host. Default is 2.
- MaxPipeline = integer()
  Maximum number of outstanding requests on the same connection to a host. Default is 2.
- PipelineTimeout = integer()
  If a persistent connection is idle longer than the pipeline_timeout the client will close the connection. Default is 0. The server may also have a such a time out but you should not count on it!
- CookieMode = enabled | disabled | verify
  Default is disabled. If Cookies are enabled all valid cookies will automatically be saved in the client manager’s cookie database. If the option verify is used the function http:verify_cookie/2 has to be called for the cookie to be saved.
-Ipv6Mode = enabled | disabled
  By default enabled. This should normally be what you want. When it is enabled you can use both ipv4 and ipv6. The option is here to provide a workaround for buggy ipv6 stacks to ensure that ipv4 will always work.
Sets options to be used for subsequent requests. Later implementations may support user profiles, but currently these are global settings for all clients running on the same erlang node.

**Note:**
If possible the client will keep its connections alive and use them to pipeline requests whenever the circumstances allow. The HTTP/1.1 specification does not provide a guideline for how many requests that would be ideal to pipeline, this very much depends on the application. Note that a very long pipeline may cause a user perceived delays as earlier request may take a long time to complete. The HTTP/1.1 specification does suggest a limit of 2 persistent connections per server, which is the default value of the max_sessions option.

```erlang
verify_cookie(SetCookieHeaders, Url) -> ok
```

**Types:**
- `SetCookieHeaders = headers() - where field = "set-cookie"
- `Url = url()

Saves the cookies defined in SetCookieHeaders in the client manager's cookie database. You need to call this function if you set the option cookies to verify.

```erlang
cookie_header(Url) -> header()
```

**Types:**
- `Url = url()

Returns the cookie header that would be sent when making a request to `Url`.

**SEE ALSO**

RFC 2616, [ssl(3)]
http_base_64

Erlang Module

Implements base 64 encode and decode, see RFC 2045.

COMMON DATA TYPES

Here follows type definitions that are used by more than once this module.

string() = list of ASCII characters

Exports

encode(PlainASCII) -> Base64

Types:
- PlainASCII = string()
- Base64 = string()

Encodes a plain ASCII string into base64.

decode(Base64) -> PlainASCII

Types:
- PlainASCII = string()
- Base64 = string()

Decodes an base64 encoded string to plain ASCII.
Mainly specifies the Erlang Webserver callback API but also provide some test and admin. functionality.

DATA TYPES

ModData = #mod{} -record(mod, {data = [],
  socket_type = ip_comm,
  socket,
  config_db,
  method,
  absolute_uri,
  request_uri,
  http_version,
  request_line,
  parsed_header = [],
  entity_body,
  connection
}).

The fields of the mod record has the following meaning:

data  Type [[InteractionKey,InteractionValue]] is used to propagate data between modules. Depicted interaction_data() in function type declarations.
socket_type  socket_type(), Indicates whether it is a ip socket or a ssl socket.
socket  The actual socket in ip_comm or ssl format depending on the socket_type.
config_db  The config file directives stored as key-value tuples in an ETS-table. Depicted config_db() in function type declarations.
method  Type "GET" | "POST" | "HEAD" | "TRACE", that is the HTTP metod.
absolute_uri  If the request is a HTTP/1.1 request the URI might be in the absolute URI format. In that case httpd will save the absolute URI in this field. An Example of an absolute URI could be "http://ServerName:Part/cgi-bin/find.pl?person=jocke"
request_uri  The Request-URI as defined in RFC 1945, for example "/cgi-bin/find.pl?person=jocke"
http_version  The HTTP version of the request, that is "HTTP/0.9", "HTTP/1.0", or "HTTP/1.1".
The Request-Line as defined in RFC 1945, for example "GET /cgi-bin/find.pl?person=jocke HTTP/1.0".

The Request-Line contains the method used by the client to request a resource, the URI of the resource, and the HTTP version used for the request.

The parsed header Type [[HeaderKey,HeaderValue]], parsed header contains all HTTP header fields from the HTTP-request stored in a list as key-value tuples. See RFC 2616 for a listing of all header fields. For example the date field would be stored as: "date","Wed, 15 Oct 1997 14:35:17 GMT". RFC 2616 defines that HTTP is a case insensitive protocol and the header fields may be in lowercase or upper case. Httpd will ensure that all header field names are in lowercase.

The Entity-Body as defined in RFC 2616, for example data sent from a CGI-script using the POST method.

connection true | false If set to true the connection to the client is a persistent connection and will not be closed when the request is served.

The Entity-Body contains the data sent back to the client as part of the response. This could be anything from XML data to a simple HTML page.

Erlang Webserver API Callback Functions

Exports

Module:do(ModData) -> {proceed,OldData} | {proceed,NewData} | {break,NewData} | done

Types:
-OldData = list()
-NewData = [{response,[StatusCode,Body]]} | [{response,[response,Head,Body2]]} | [{response,[already_sent,StatusCode,Size]]}
-StatusCode = integer()
-Body = iolist() | nobody | {Fun,Arg}
-Head = [{HeaderOption}]
-HeaderOption = {Key,Value} | {code,StatusCode}
-Key = allow | cache_control | content_MD5 | content_encoding | content_encoding | content_label | content_language | content_md5 | content_md5 | content_range | content_type | content_date | content_md5 | content_expires | content_last_modified | location | pragma | retry_after | server | trailer | transfer_encoding
-Value = string()
-Fun = fun( Arg ) -> sent | close | Body
-Arg = [term()]

When a valid request reaches httpd it calls do/1 in each module defined by the Modules configuration directive. The function may generate data for other modules or a response that can be sent back to the client.

The field data in ModData is a list. This list will be the list returned from the from the last call to do/1.

Body is the body of the http-response that will be sent back to the client an appropriate header will be appended to the message. StatusCode will be the status code of the response see RFC2616 for the appropriate values.

Head is a key value list of HTTP header fields. the server will construct a HTTP header from this data. See RFC 2616 for the appropriate values for each header field. If the
client is a HTTP/1.0 client then the server will filter the list so that only HTTP/1.0 header fields will be sent back to the client.

If Body2 is returned and equal to \{Fun, Arg\} The Web server will try apply/2 on Fun with Arg as argument and expect that the fun either returns a list (Body) that is a HTTP-repsonse or the atom sent if the HTTP-response is sent back to the client. If close is returned from the fun something has gone wrong and the server will signal this to the client by closing the connection.

Module:load(Line, Context) -> eof | ok | \{ok, NewContext\} | \{ok, NewContext, Directive\} | \{ok, NewContext, DirectiveList\} | \{error, Reason\}

Types:
- Line = string()
- Directive = (DirectiveKey, DirectiveValue)
- DirectiveKey = DirectiveValue = term()
- Reason = term()

load/2 takes a row Line from the configuration file and tries to convert it to a key value tuple. If a directive is dependent on other directives, the directive may create a context. If the directive is not dependent on other directives return \{ok, [], Directive\}, otherwise return a new context, that is \{ok, NewContext\} or \{ok, Context Directive\}. If \{error, Reason\} is returned the configuration directive is assumed to be invalid.

Types:
- DirectiveKey = DirectiveValue = term()
- Directive = \{Key, Value\}
- Reason = term()

When all rows in the configuration file is read the function store/2 is called for each configuration directive. This makes it possible for a directive to alter other configuration directives. DirectiveList is a list of all configuration directives read in from load. If a directive may update other configuration directives then use this function.

Module:remove(ConfigDB) -> ok | \{error, Reason\}

Types:
- ConfigDB = ets_table()
- Reason = term()

When httpd shutdown it will try to execute remove/1 in each ewsapi module. The ewsapi programmer may use this to close ets tables, save data, or close down background processes.
Erlang Webserver API Help Functions

Exports

parse_query(QueryString) -> ServerRet

Types:
- QueryString = string()
- ServerRet = [{Key,Value}]
- Key = Value = string()

parse_query/1 parses incoming data to erl and eval scripts (See mod_esi(3) [page 76]) as defined in the standard URL format, that is '+' becomes 'space' and decoding of hexadecimal characters (%xx).

Erlang Webserver Test and Admin Functions

Exports

start()
start(Config) -> ServerRet
start_link()
start_link(Config) -> ServerRet

Types:
- Config = string() | HttpdOptions
- ServerRet = {ok,Pid} | ignore | {error,REason} | {stop,SReason}
- Pid = pid()
- REason = {already_started, Pid} | term()
- SReason = string()
- HttpdOptions = {file,string()} | {debug,Debug} | {accept_timeout,integer()} |
  {disable,HttpdOptions}
  {all_functions,Modules} | {exported_functions,Modules} | |
  {disable,HttpdOptions}
- Modules = [atom()]

start/1 and start_link/1 starts a server as specified in the given ConfigFile. The ConfigFile supports a number of config directives specified below.

start/0 and start/0 starts a server as specified in a hard-wired config file, that is

start("/var/tmp/server_root/conf/8888.conf"). Before utilizing start/0 or
start_link/0, copy the example server root\(^1\) to a specific installation directory\(^2\) and
you have a server running in no time.

If you copy the example server root to the specific installation directory it is
furthermore easy to start an SSL enabled server, that is

start("/var/tmp/server_root/conf/ssl.conf").

\(^1\)In Windows: %INETS_ROOT%\examples\server_root. In UNIX: $INETS_ROOT/examples/server_root/.
\(^2\)In Windows: X:\var\tmp\. In UNIX: /var/tmp/.
restart()  
restart(Port) -> ok | {error,Reason}  
restart(ConfigFile) -> ok | {error,Reason}  
restart(Address,Port) -> ok | {error,Reason}  

Types:

- Port = integer()  
- Address = [A,B,C,D] | string() | undefined  
- ConfigFile = string()  
- Reason = term()  

restart restarts the server and reloads its config file.  
The following directives cannot be changed: BindAddress, Port and SocketType. If these  
should be changed, then a new server should be started instead.  

Note:  
Before the restart function can be called the server must be blocked [page 59].  
After restart has been called, the server must be unblocked [page 59].  

stop()  
stop(Port) -> ServerRet  
stop(ConfigFile) -> ServerRet  
stop(Address,Port) -> ServerRet  

Types:  

- Port = integer()  
- Address = [A,B,C,D] | string() | undefined  
- ConfigFile = string()  
- ServerRet = ok | not_started  

stop/2 stops the server which listens to the specified Port on Address.  
stop(integer()) stops a server which listens to a specific Port. stop(string())  
evaluates BindAddress and Port from the config file and stops the server which listens to  
the specified Port on Address. stop/0 stops a server which listens to port 8888, that is  
stop(8888).  

block() -> ok | {error,Reason}  
block(Port) -> ok | {error,Reason}  
block(ConfigFile) -> ok | {error,Reason}  
block(Address,Port) -> ok | {error,Reason}  
block(Port,Mode) -> ok | {error,Reason}  
block(ConfigFile,Mode) -> ok | {error,Reason}  
block(Address,Port,Mode) -> ok | {error,Reason}  
block(ConfigFile,Mode,Timeout) -> ok | {error,Reason}  
block(Address,Port,Mode,Timeout) -> ok | {error,Reason}  

Types:  

- Port = integer()
This function is used to block a server. The blocking can be done in two ways, disturbing or non-disturbing.

By performing a disturbing block, the server is blocked forcefully and all ongoing requests are terminated. No new connections are accepted. If a timeout time is given then on-going requests are given this much time to complete before the server is forcefully blocked. In this case no new connections is accepted.

A non-disturbing block is more graceful. No new connections are accepted, but the ongoing requests are allowed to complete. If a timeout time is given, it waits this long before giving up (the block operation is aborted and the server state is once more not-blocked)

Default mode is disturbing.
Default port is 8888

unblock() -> ok | {error,Reason}
unblock(Port) -> ok | {error,Reason}
unblock(ConfigFile) -> ok | {error,Reason}
unblock(Address,Port) -> ok | {error,Reason}

Types:
- Port = integer()
- Address = {A,B,C,D} | string() | undefined
- ConfigFile = string()
- Reason = term()

Unblocks a server. If the server is already unblocked this is a no-op. If a block is ongoing, then it is aborted (this will have no effect on ongoing requests).
httpd_conf

Erlang Module

This module provides the Erlang Webserver API programmer with utility functions for adding run-time configuration directives.

Exports

check_enum(EnumString,ValidEnumStrings) -> Result
Types:
  - EnumString = string()
  - ValidEnumStrings = [string()]
  - Result = {ok,atom()} | {error,not_valid}
check_enum/2 checks if EnumString is a valid enumeration of ValidEnumStrings in which case it is returned as an atom.

clean(String) -> Stripped
Types:
  - String = Stripped = string()
clean/1 removes leading and/or trailing white spaces from String.

custom_clean(String,Before,After) -> Stripped
Types:
  - Before = After = regexp()
  - String = Stripped = string()
custom_clean/3 removes leading and/or trailing white spaces and custom characters from String. Before and After are regular expressions, as defined in regexp(3), describing the custom characters.

is_directory(FilePath) -> Result
Types:
  - FilePath = string()
  - Result = {ok,Directory} | {error,Reason}
  - Directory = string()
  - Reason = string() | enoent | eaccess | enotdir | FileInfo
  - FileInfo = File info record
is_directory/1 checks if FilePath is a directory in which case it is returned. Please read file(3) for a description of enoent, eaccess and enotdir. The definition of the file info record can be found by including file.hrl from the kernel application, see file(3).

is_file(FilePath) -> Result

Types:
- FilePath = string()
- Result = {ok,File} | {error,Reason}
- File = string()
- Reason = string() | enoent | eaccess | enotdir | FileInfo
- FileInfo = File info record

is_file/1 checks if FilePath is a regular file in which case it is returned. Read file(3) for a description of enoent, eaccess and enotdir. The definition of the file info record can be found by including file.hrl from the kernel application, see file(3).

make_integer(String) -> Result

Types:
- String = string()
- Result = {ok,integer()} | {error,nomatch}

make_integer/1 returns an integer representation of String.

SEE ALSO

httpd(3) [page 54]
httpd_socket

Erlang Module

This module provides the Erlang Webserver API module programmer with utility functions for generic sockets communication. The appropriate communication mechanism is transparently used, that is \texttt{ip\_comm} or \texttt{ssl}.

Exports

\begin{verbatim}
deliver(SocketType, Socket, Data) -> Result

Types:
  • SocketType = socket_type()
  • Socket = socket()
  • Data = io_list() | binary()
  • Result = socket_closed | void()

deliver/3 sends the Binary over the Socket using the specified SocketType. Socket and SocketType should be the socket and the socket_type form the mod record as defined in \texttt{httpd.hrl}

peername(SocketType,Socket) -> \{Port,IPAddress\}

Types:
  • SocketType = socket_type()
  • Socket = socket()
  • Port = integer()
  • IPAddress = string()

peername/3 returns the Port and IPAddress of the remote Socket.

resolve() -> HostName

Types:
  • HostName = string()

resolve/0 returns the official HostName of the current host.
\end{verbatim}

SEE ALSO

\texttt{httpd(3)} [page 54]
httpd_util

Erlang Module

This module provides the Erlang Web Server API module programmer with miscellaneous utility functions.

Exports

convert_request_date(DateString) -> ErlDate|bad_date

Types:
- DateString = string()
- ErlDate = {Year,Month,Date},{Hour,Min,Sec}
- Year = Month = Date = Hour = Min = Sec = integer()

convert_request_date/1 converts DateString to the Erlang date format. DateString must be in one of the three date formats that is defined in the RFC 2616.

create_etag(FileInfo) -> Etag

Types:
- FileInfo = file_info()
- Etag = string()

create_etag/1 calculates the Etag for a file, from it's size and time for last modification. fileinfo is a record defined in kernel/include/file.hrl.

decode_base64(Base64String) -> ASCIIString

Types:
- Base64String = ASCIIString = string()

Deprecated use http_base64:decode/1 [page 53]

decode_hex(HexValue) -> DecValue

Types:
- HexValue = DecValue = string()

Converts the hexadecimal value HexValue into it's decimal equivalent (DecValue).

day(NthDayOfWeek) -> DayOfWeek

Types:
- NthDayOfWeek = 1-7
- DayOfWeek = string()
day/1 converts the day of the week (NthDayOfWeek) as an integer (1-7) to an abbreviated string, that is:
1 = “Mon”, 2 = “Tue”, ..., 7 = “Sat”.

encode_base64(ASCIIString) -> Base64String
Types:
- ASCIIString = string()
- Base64String = string()
Deprecated use http_base64:decode/1 [page 53]

flatlength(NestedList) -> Size
Types:
- NestedList = list()
- Size = integer()
flatlength/1 computes the size of the possibly nested list NestedList. Which may contain binaries.

header(StatusCode,PersistentConn)
header(StatusCode,Date)
header(StatusCode,MimeType,Date)
header(StatusCode,MimeType,PersistentConn,Date) -> HTTPHeader
Types:
- StatusCode = integer()
- Date = rfc1123 date()
- MimeType = string()
- PersistentConn = true | false

header returns a HTTP 1.1 header string. The StatusCode is one of the status codes defined in RFC 2616 and the Date string is RFC 1123 compliant. (See rfc1123_date/0 [page 67]).
Note that the two version of header/n that does not has a PersistentConn argument is there only for backward compability, and must not be used in new Erlang Webserver API modules that will support persistent connections.

hexlist_to_integer(HexString) -> Number
Types:
- Number = integer()
- HexString = string()
hexlist_to_integer Convert the Hexadecimal value of HexString to an integer.

integer_tohexlist(Number) -> HexString
Types:
- Number = integer()
- HexString = string()
integer_to_hexlist/1 Returns a string that represents the number in a hexadecimal form.

key1search(TupleList, Key)
key1search(TupleList, Key, Undefined) -> Result

Types:
· TupleList = [tuple(] 
· Key = term()
· Result = term() | undefined | Undefined
· Undefined = term()

key1search searches the TupleList for a tuple whose first element is Key. 
key1search/2 returns undefined and key1search/3 returns Undefined if no tuple is found.

lookup(ETSTable, Key) -> Result
lookup(ETSTable, Key, Undefined) -> Result

Types:
· ETSTable = ets_table()
· Key = term()
· Result = term() | undefined | Undefined
· Undefined = term()

lookup extracts {Key, Value} tuples from ETSTable and returns the Value associated with Key. If ETSTable is of type bag only the first Value associated with Key is returned. 
lookup/2 returns undefined and lookup/3 returns Undefined if no Value is found.

lookup_mime(ConfigDB, Suffix)
lookup_mime(ConfigDB, Suffix, Undefined) -> MimeType

Types:
· ConfigDB = ets_table()
· Suffix = string()
· MimeType = string() | undefined | Undefined
· Undefined = term()

lookup_mime returns the mime type associated with a specific file suffix as specified in the mime.types file (located in the config directory).

lookup_mime_default(ConfigDB, Suffix)
lookup_mime_default(ConfigDB, Suffix, Undefined) -> MimeType

Types:
· ConfigDB = ets_table()
· Suffix = string()
· MimeType = string() | undefined | Undefined
· Undefined = term()

3In Windows: %SERVER_ROOT%\conf\mime.types. In UNIX: $SERVER_ROOT/conf/mime.types.
lookup_mime_default returns the mime type associated with a specific file suffix as specified in the mime.types file (located in the config directory\(^4\)). If no appropriate association can be found the value of DefaultType is returned.

message(StatusCode,PhraseArgs,ConfigDB) -> Message

Types:
- StatusCode = 301 | 400 | 403 | 404 | 500 | 501 | 504
- PhraseArgs = term()
- ConfigDB = ets_table
- Message = string()

message/3 returns an informative HTTP 1.1 status string in HTML. Each StatusCode requires a specific PhraseArgs:

301 string(): A URL pointing at the new document position.
400 | 401 | 500 none (No PhraseArgs)
403 | 404 string(): A Request-URI as described in RFC 2616.
501 {Method,RequestURI,HTTPVersion}: The HTTP Method, Request-URI and HTTP-Version as defined in RFC 2616.
504 string(): A string describing why the service was unavailable.

month(NthMonth) -> Month

Types:
- NthMonth = 1-12
- Month = string()

month/1 converts the month NthMonth as an integer (1-12) to an abbreviated string, that is:
1 = “Jan”, 2 = “Feb”, ..., 12 = “Dec”.

multi_lookup(ETSTable,Key) -> Result

Types:
- ETSTable = ets_table()
- Key = term()
- Result = [term()]

multi_lookup extracts all \{Key,Value\} tuples from an ETSTable and returns all Values associated with the Key in a list.

reason_phrase(StatusCode) -> Description

Types:
- StatusCode = 100| 200 | 201 | 202 | 204 | 205 | 206 | 300 | 301 | 302 | 303 | 304 | 400 | 401 | 402 | 403 | 404 | 405 | 406 | 410 | 411 | 412 | 413 | 414 | 415 | 416 | 417 | 500 | 501 | 502 | 503 | 504 | 505
- Description = string()

\(^4\)In Windows: %SERVER_ROOT%\conf\mime.types. In UNIX: $SERVER_ROOT/conf/mime.types.
reason_phrase returns the Description of an HTTP 1.1 StatusCode, for example 200 is "OK" and 201 is "Created". Read RFC 2616 for further information.

rfc1123_date() -> RFC1123Date
rfc1123_date([YYYY,MM,DD],[Hour,Min,Sec])) -> RFC1123Date

Types:
- YYYY = MM = DD = Hour = Min =Sec = integer()
- RFC 1123Date = string()

rfc1123_date/0 returns the current date in RFC 1123 format. rfc1123_date/1 converts the date in the Erlang format to the RFC 1123 date format.

split(String,RegExp,N) -> SplitRes

Types:
- String = RegExp = string()
- SplitRes = {ok, FieldList} | {error, errordesc()}
- Fieldlist=[string()]
- N = integer

split/3 splits the string in N chunks using the RegExp. split/3 is is equivalent to regexp:split/2 with one exception, that is N defines the number of maximum number of fields in the FieldList.

split_script_path(RequestLine) -> Splitted

Types:
- RequestLine = string()
- Splitted = not_a_script | {Path, PathInfo, QueryString}
- Path = QueryString = PathInfo = string()

split_script_path/1 is equivalent to split_path/1 with one exception. If the longest possible path is not a regular, accessible and executable file not_a_script is returned.

split_path(RequestLine) -> {Path,QueryStringOrPathInfo}

Types:
- RequestLine = Path = QueryStringOrPathInfo = string()

split_path/1 splits the RequestLine in a file reference (Path) and a QueryString or a PathInfo string as specified in RFC 2616. A QueryString is isolated from the Path with a question mark (?) and PathInfo with a slash (/). In the case of a QueryString, everything before the ? is a Path and everything after a QueryString. In the case of a PathInfo the RequestLine is scanned from left-to-right on the hunt for longest possible Path being a file or a directory. Everything after the longest possible Path, isolated with a /, is regarded as PathInfo. The resulting Path is decoded using decode_hex/1 before delivery.

strip(String) -> Stripped

Types:
- String = Stripped = string()
strip/1 removes any leading or trailing linear white space from the string. Linear white space should be read as horizontal tab or space.

`suffic(FileName) -> Suffix`

Types:
- `FileName = Suffix = string()`

`suffix/1` is equivalent to `filename:extension/1` with one exception, that is `Suffix` is returned without a leading dot (..).

`to_lower(String) -> ConvertedString`

Types:
- `String = ConvertedString = string()`

`to_lower/1` converts upper-case letters to lower-case.

`to_upper(String) -> ConvertedString`

Types:
- `String = ConvertedString = string()`

`to_upper/1` converts lower-case letters to upper-case.

**SEE ALSO**

httpd(3) [page 54]
mod_alias

Erlang Module

Erlang Webserver Server internal API for handling of things such as interaction data exported by the mod_alias module.

Exports

default_index(ConfigDB, Path) -> NewPath

Types:
- ConfigDB = config_db()
- Path = NewPath = string()

If Path is a directory, default_index/2, it starts searching for resources or files that are specified in the config directive DirectoryIndex. If an appropriate resource or file is found, it is appended to the end of Path and then returned. Path is returned unaltered, if no appropriate file is found, or if Path is not a directory. config_db() is the server config file in ETS table format as described in Inets Users Guide. [page 4].

path(PathData, ConfigDB, RequestURI) -> Path

Types:
- PathData = interaction_data()
- ConfigDB = config_db()
- RequestURI = Path = string()

path/3 returns the actual file Path in the RequestURI (See RFC 1945). If the interaction data \{real_name,\{Path,AfterPath\}\} has been exported by mod_alias, Path is returned. If no interaction data has been exported, ServerRoot is used to generate a file Path. config_db() and interaction_data() are as defined in Inets Users Guide [page 4].

real_name(ConfigDB, RequestURI, Aliases) -> Ret

Types:
- ConfigDB = config_db()
- RequestURI = string()
- Aliases = [[FakeName,RealName]]
- Ret = \{ShortPath,Path,AfterPath\}
- ShortPath = Path = AfterPath = string()
real_name/3 traverses Aliases, typically extracted from ConfigDB, and matches each FakeName with RequestURI. If a match is found FakeName is replaced with RealName in the match. The resulting path is split into two parts, that is ShortPath and AfterPath as defined in httpd_util:split_path/1 [page 67]. Path is generated from ShortPath, that is the result from default_index/2 [page 69] with ShortPath as an argument.

config_db() is the server config file in ETS table format as described in Inets User Guide [page 4].

real_script_name(ConfigDB, RequestURI, ScriptAliases) -> Ret

Types:
- ConfigDB = config_db()
- RequestURI = string()
- ScriptAliases = [{FakeName, RealName}]
- Ret = {ShortPath, AfterPath} | not_a_script
- ShortPath = AfterPath = string()

real_name/3 traverses ScriptAliases, typically extracted from ConfigDB, and matches each FakeName with RequestURI. If a match is found FakeName is replaced with RealName in the match. If the resulting match is not an executable script not_a_script is returned. If it is a script the resulting script path is in two parts, that is ShortPath and AfterPath as defined in httpd_util:split_script_path/1 [page 67]. config_db() is the server config file in ETS table format as described in Inets User Guide [page 4].
mod_auth

Erlang Module

This module provides for basic user authentication using textual files, dets databases as well as mnesia databases.

Exports

add_user(UserName, Options) -> true | {error, Reason}
add_user(UserName, Password, UserData, Port, Dir) -> true | {error, Reason}
add_user(UserName, Password, UserData, Address, Port, Dir) -> true | {error, Reason}

Types:
- UserName = string()
- Options = [Option]
- Option = [password,Password] | [userD ata,UserD ata] | [port,Port] | [addr,A ddress] | [dir,D irectory] | [authPassword,AuthPassword]
- Password = string()
- UserData = term()
- Port = integer()
- Address = [A,B,C,D ] | string() | undefined
- Dir = string()
- AuthPassword = string()
- Reason = term()

add_user/2, add_user/5 and add_user/6 adds a user to the user database. If the operation is successful, this function returns true. If an error occurs, {error,Reason} is returned. When add_user/2 is called the Password, UserData Port and Dir options is mandatory.

delete_user(UserName,Options) -> true | {error, Reason}
delete_user(UserName, Port, Dir) -> true | {error, Reason}
delete_user(UserName, Address, Port, Dir) -> true | {error, Reason}

Types:
- UserName = string()
- Options = [Option]
- Option = [port,Port] | [addr,A ddress] | [dir,D irectory] | [authPassword,AuthPassword]
- Port = integer()
- Address = [A,B,C,D ] | string() | undefined
- Dir = string()
delete_user/2, delete_user/3 and delete_user/4 deletes a user from the user database. If the operation is successful, this function returns true. If an error occurs, {error, Reason} is returned. When delete_user/2 is called the Port and Dir options are mandatory.

get_user(UserName, Options) -> {ok, #httpd_user} | {error, Reason}  
get_user(UserName, Port, Dir) -> {ok, #httpd_user} | {error, Reason}  
get_user(UserName, Address, Port, Dir) -> {ok, #httpd_user} | {error, Reason}  

Types:
- UserName = string()
- Options = [Option]
- Option = {port, Port} | {addr, Address} | {dir, Directory} | {authPassword, AuthPassword}
- Port = integer()
- Address = {A, B, C, D} | string() | undefined
- Dir = string()
- AuthPassword = string()
- Reason = term()

get_user/2, get_user/3 and get_user/4 returns a httpd_user record containing the userdata for a specific user. If the user cannot be found, {error, Reason} is returned. When get_user/2 is called the Port and Dir options are mandatory.

list_users(Options) -> {ok, Users} | {error, Reason}
list_users(Port, Dir) -> {ok, Users} | {error, Reason}
list_users(Address, Port, Dir) -> {ok, Users} | {error, Reason}

Types:
- Options = [Option]
- Option = {port, Port} | {addr, Address} | {dir, Directory} | {authPassword, AuthPassword}
- Port = integer()
- Address = {A, B, C, D} | string() | undefined
- Dir = string()
- Users = list()
- AuthPassword = string()
- Reason = atom()

list_users/1, list_users/2 and list_users/3 returns a list of users in the user database for a specific Port/Dir. When list_users/1 is called the Port and Dir options are mandatory.

add_group_member(GroupName, UserName, Options) -> true | {error, Reason}  
add_group_member(GroupName, UserName, Port, Dir) -> true | {error, Reason}  
add_group_member(GroupName, UserName, Address, Port, Dir) -> true | {error, Reason}  

Types:
- GroupName = string()
Inets Reference Manual

- **UserName = string()**
- **Options = [Option]**
- **Option = {port,Port} | {addr,Address} | {dir,Directory} | {authPassword,AuthPassword}**
- **Port = integer()**
- **Address = {A,B,C,D} | string() | undefined**
- **Dir = string()**
- **AuthPassword = string()**
- **Reason = term()**

`add_group_member/3`, `add_group_member/4` and `add_group_member/5` adds a user to a group. If the group does not exist, it is created and the user is added to the group. Upon successful operation, this function returns true. When `add_group_members/3` is called the Port and Dir options are mandatory.

```prolog
add_group_member(GroupName, UserName, Options) -> true | {error, Reason}
add_group_member(GroupName, UserName, Port, Dir) -> true | {error, Reason}
add_group_member(GroupName, UserName, Address, Port, Dir) -> true | {error, Reason}
```

**Types:**
- **GroupName = string()**
- **UserName = string()**
- **Options = [Option]**
- **Option = {port,Port} | {addr,Address} | {dir,Directory} | {authPassword,AuthPassword}**
- **Port = integer()**
- **Address = {A,B,C,D} | string() | undefined**
- **Dir = string()**
- **AuthPassword = string()**
- **Reason = term()**

`delete_group_member/3`, `delete_group_member/4` and `delete_group_member/5` deletes a user from a group. If the group or the user does not exist, this function returns an error, otherwise it returns true. When `delete_group_member/3` is called the Port and Dir options are mandatory.

```prolog
delete_group_member(GroupName, UserName, Options) -> true | {error, Reason}
delete_group_member(GroupName, UserName, Port, Dir) -> true | {error, Reason}
delete_group_member(GroupName, UserName, Address, Port, Dir) -> true | {error, Reason}
```

**Types:**
- **GroupName = string()**
- **UserName = string()**
- **Options = [Option]**
- **Option = {port,Port} | {addr,Address} | {dir,Directory} | {authPassword,AuthPassword}**
- **Port = integer()**
- **Address = {A,B,C,D} | string() | undefined**
- **Dir = string()**
- **Users = list()**

`list_group_members(GroupName, Options) -> {ok, Users} | {error, Reason}`
`list_group_members(GroupName, Port, Dir) -> {ok, Users} | {error, Reason}`
`list_group_members(GroupName, Address, Port, Dir) -> {ok, Users} | {error, Reason}`

**Types:**
- **GroupName = string()**
- **Options = [Option]**
- **Option = {port,Port} | {addr,Address} | {dir,Directory} | {authPassword,AuthPassword}**
- **Port = integer()**
- **Address = {A,B,C,D} | string() | undefined**
- **Dir = string()**
- **Users = list()**
- AuthPassword = string()
- Reason = term()

list_group_members/2, list_group_members/3 and list_group_members/4 lists the members of a specified group. If the group does not exist or there is an error, \{error, Reason\} is returned. When list_group_members/2 is called the Port and Dir options are mandatory.

list_groups(Options) -> \{ok, Groups\} | \{error, Reason\}
list_groups(Port, Dir) -> \{ok, Groups\} | \{error, Reason\}
list_groups(Address, Port, Dir) -> \{ok, Groups\} | \{error, Reason\}

Types:
- Options = \{Option\}
- Option = \{port,Port\} | \{addr,Address\} | \{dir,Directory\} | \{authPassword,AuthPassword\}
- Port = integer()
- Address = \{A,B,C,D\} | string() | undefined
- Dir = string()
- Groups = list()
- AuthPassword = string()
- Reason = term()

list_groups/1, list_groups/2 and list_groups/3 lists all the groups available. If there is an error, \{error, Reason\} is returned. When list_groups/1 is called the Port and Dir options are mandatory.

delete_group(GroupName, Options) -> true | \{error,Reason\}
<name>delete_group(GroupName, Port, Dir) -> true | \{error, Reason\}
delete_group(GroupName, Address, Port, Dir) -> true | \{error, Reason\}

Types:
- Options = \{Option\}
- Option = \{port,Port\} | \{addr,Address\} | \{dir,Directory\} | \{authPassword,AuthPassword\}
- Port = integer()
- Address = \{A,B,C,D\} | string() | undefined
- Dir = string()
- GroupName = string()
- AuthPassword = string()
- Reason = term()

delete_group/2, delete_group/3 and delete_group/4 deletes the group specified and returns true. If there is an error, \{error, Reason\} is returned. When delete_group/2 is called the Port and Dir options are mandatory.

update_password(Port, Dir, OldPassword, NewPassword, NewPassword) -> ok | \{error, Reason\}
update_password(Address,Port, Dir, OldPassword, NewPassword, NewPassword) -> ok | \{error, Reason\}

Types:
update_password/5 and update_password/6 Updates the AuthAccessPassword for the specified directory. If NewPassword is equal to "NoPassword" no password is requires to change authorisation data. If NewPassword is equal to "DummyPassword" no changes can be done without changing the password first.

SEE ALSO

httpd(3) [page 54], mod_alias(3) [page 69],
mod_esi

Erlang Module

This module defines the API - Erlang Server Interface (ESI). Which is a more efficient way of writing erlang scripts for your Inets webserver than writing them as common CGI scripts.

Exports

deliver(SessionID, Data) -> ok | {error, Reason}

Types:
- SessionID = term()
- Data = string() | io_list()
- Reason = term()

This function is only intended to be used from functions called by the Erl Scheme interface to deliver parts of the content to the user.

Sends data from a Erl Scheme script back to the client. Note that if any HTTP-header fields should be added by the script they must be in the first call to deliver/2 and the data in the call must be a string. Do not assume anything about the data type of SessionID, the SessionID must be the value given as input to the esi call back function that you implemented.

ESI Callback Functions

Exports

Module:Function(SessionID, Env, Input) -> _

Types:
- SessionID = term()
- Env = [EnvironmentDirectives] ++ ParsedHeader
- EnvironmentDirectives = {Key,Value}
- Key = query_string | content_length | server_software | gateway_interface | server_protocol | server_port | request_method | remote_addr | script_name.
- Input = string()
The Module must be found in the code path and export Function with an arity of two. An erlScriptAlias must also be set up in the configuration file for the Web server.

If the HTTP request is a post request and a body is sent then content_length will be the length of the posted data. If get is used query_string will be the data after ? in the url.

ParsedHeader is the HTTP request as a key value tuple list. The keys in parsed header will be the in lower case.

SessionID is a identifier the server use when deliver/2 is called, do not assume any-thing about the datatype.

Use this callback function to dynamically generate dynamic web content. when a part of the page is generated send the data back to the client through deliver/2. Note that the first chunk of data sent to the client must at least contain all HTTP header fields that the response will generate. If the first chunk not contains End of HTTP header that is "\r\n\r\n" the server will assume that no HTTP header fields will be generated.

Module:Function(Env, Input) -> Response

Types:
- Env = [EnvironmentDirectives] ++ ParsedHeader
- EnvironmentDirectives = {Key,Value}
- Key = query_string | content_length | server_software | gateway_interface | server_protocol | server_port | request_method | remote_addr | script_name.
- Input = string()
- Response = string()

This callback format consumes quite much memory since the whole response must be generated before it is sent to the user. This functions is deprecated and only keept for backwards compability. For new development Module:Function/3 should be used.
mod_security

Erlang Module

Security Audit and Trailing Functionality

Exports

\[ \text{list_auth_users(Port)} \rightarrow \text{Users} | [] \]
\[ \text{list_auth_users(Address, Port)} \rightarrow \text{Users} | [] \]
\[ \text{list_auth_users(Port, Dir)} \rightarrow \text{Users} | [] \]
\[ \text{list_auth_users(Address, Port, Dir)} \rightarrow \text{Users} | [] \]

Types:
- \( \text{Port} = \text{integer}() \)
- \( \text{Address} = \{A,B,C,D\} | \text{string}() | \text{undefined} \)
- \( \text{Dir} = \text{string}() \)
- \( \text{Users} = \text{list}() = [\text{string}()] \)

\text{list_auth_users/1, list_auth_users/2 and list_auth_users/3} returns a list of users that are currently authenticated. Authentications are stored for SecurityAuthTimeout seconds, and are then discarded.

\[ \text{list_blocked_users(Port)} \rightarrow \text{Users} | [] \]
\[ \text{list_blocked_users(Address, Port)} \rightarrow \text{Users} | [] \]
\[ \text{list_blocked_users(Port, Dir)} \rightarrow \text{Users} | [] \]
\[ \text{list_blocked_users(Address, Port, Dir)} \rightarrow \text{Users} | [] \]

Types:
- \( \text{Port} = \text{integer}() \)
- \( \text{Address} = \{A,B,C,D\} | \text{string}() | \text{undefined} \)
- \( \text{Dir} = \text{string}() \)
- \( \text{Users} = \text{list}() = [\text{string}()] \)

\text{list_blocked_users/1, list_blocked_users/2 and list_blocked_users/3} returns a list of users that are currently blocked from access.

\[ \text{block_user(User, Port, Dir, Seconds)} \rightarrow \text{true} | \{\text{error}, \text{Reason}\} \]
\[ \text{block_user(User, Address, Port, Dir, Seconds)} \rightarrow \text{true} | \{\text{error}, \text{Reason}\} \]

Types:
- \( \text{User} = \text{string}() \)
- \( \text{Port} = \text{integer}() \)
- \( \text{Address} = \{A,B,C,D\} | \text{string}() | \text{undefined} \)
unblock_user/2, unblock_user/3 and unblock_user/4 removes the user User from the list of blocked users for the Port (and Dir) specified.

The SecurityCallbackModule

The SecurityCallbackModule is a user written module that can receive events from the mod_security Erlang Webserver API module. This module only exports one function, event/4 [page 79], which is described below.

Exports

event(What, Port, Dir, Data) -> ignored
event(What, Address, Port, Dir, Data) -> ignored

Types:
- What = atom()
- Port = integer()
- Address = [A,B,C,D] | string() | undefined
- Dir = string()
- Reason = term()

event/4 or event/5 is called whenever an event occurs in the mod_security Erlang Webservice API module (event/4 is called if Address is undefined and event/5 otherwise). The What argument specifies the type of event that has occurred, and should be one of the following reasons: auth_fail (a failed user authentication), user_block (a user is being blocked from access) or user_unblock (a user is being removed from the block list).
Note:
Note that the user_unblock event is not triggered when a user is removed from the block list explicitly using the unblock_user function.
