Chapter 1

Getting Started With Erlang

1.1 Introduction

1.1.1 Introduction

This is a “kick start” tutorial to get you started with Erlang. Everything here is true, but only part of the
thrust. For example, I’ll only tell you the simplest form of the syntax, not all esoteric forms. Where I’ve
greatly oversimplified things I’ll write *manual* which means there is lots more information to be found

I also assume that this isn’t the first time you have touched a computer and you have a basic idea about
how they are programmed. Don’t worry, I won’t assume you’re a wizard programmer.

1.1.2 Things Left Out

In particular the following has been omitted:

- References
- Local error handling (catch/throw)
- Single direction links (monitor)
- Handling of binary data (binaries / bit syntax)
- List comprehensions
- How to communicate with the outside world and/or software written in other languages (ports).
  There is however a separate tutorial for this, Interoperability Tutorial
- Very few of the Erlang libraries have been touched on (for example file handling)
- OTP has been totally skipped and in consequence the Mnesia database has been skipped.
- Hash tables for Erlang terms (ETS)
- Changing code in running systems
Chapter 1: Getting Started With Erlang

1.2 Sequential Programming

1.2.1 The Erlang Shell

Most operating systems have a command interpreter or shell; Unix and Linux have many, Windows has the Command Prompt. Erlang has its own shell where you can directly write bits of Erlang code and evaluate (run) them to see what happens (*manual*). Start the Erlang shell (in Linux or UNIX) by starting a shell or command interpreter in your operating system and typing `erl`, you will see something like this.

```
% erl
Erlang (BEAM) emulator version 5.2 [source] [hipe]
Eshell V5.2 (abort with ^G)
1>
```

Now type in “2 + 5.” as shown below.

```
1> 2 + 5.
7
2>
```

In Windows, the shell is started by double-clicking on the Erlang shell icon. You'll notice that the Erlang shell has numbered the lines that can be entered, (as 1> 2>) and that it has correctly told you that 2 + 5 is 7! Also notice that you have to tell it you are done entering code by finishing with a full stop “.” and a carriage return. If you make mistakes writing things in the shell, you can delete things by using the backspace key as in most shells. There are many more editing commands in the shell (*manual*).

(Note: you will find a lot of line numbers given by the shell out of sequence in this tutorial as it was written and the code tested in several sessions).

Now let's try a more complex calculation.

```
2> (42 + 77) * 66 / 3.
2618.00
```

Here you can see the use of brackets and the multiplication operator “*” and division operator “/”, just as in normal arithmetic (*manual*).

To shutdown the Erlang system and the Erlang shell type Control-C. You will see the following output:

```
BREAK: (a)bort (c)ontinue (p)roc info (i)nfo (l)oaded
        (v)ersion (k)ill (D)b-tables (d)istribution
a
%
```

Type “a” to leave the Erlang system.

Another way to shutdown the Erlang system is by entering `halt();`:
1.2.2 Modules and Functions

A programming language isn’t much use if you can just run code from the shell. So here is a small Erlang program. Enter it into a file called tut.erl (the file name tut.erl is important, also make sure that it is in the same directory as the one where you started erl (*manual*) using a suitable text editor. If you are lucky your editor will have an Erlang mode which will make it easier for you to enter and format your code nicely (*manual*), but you can manage perfectly well without. Here’s the code to enter:

```erlang
-module(tut).
-export([double/1]).

double(X) ->
    2 * X.
```

It’s not hard to guess that this “program” doubles the value of numbers. I’ll get back to the first two lines later. Let’s compile the program. This can be done in your Erlang shell as shown below:

```erlang
3> c(tut).
ok, tut
```

The `ok, tut` tells you that the compilation was OK. If it said “error” instead, you have made some mistake in the text you entered and there will also be error messages to give you some idea as to what has gone wrong so you can change what you have written and try again.

Now let’s run the program.

```erlang
4> tut:double(10).
20
```

As expected double of 10 is 20.

Now let’s get back to the first two lines. Erlang programs are written in files. Each file contains what we call an Erlang module. The first line of code in the module tells us the name of the module (*manual*).

```erlang
-module(tut).
```

This tells us that the module is called tut. Note the “.” at the end of the line. The files which are used to store the module must have the same name as the module but with the extension “.erl”. In our case the file name is tut.erl. When we use a function in another module, we use the syntax, `module_name:function_name(arguments)`. So

```erlang
4> tut:double(10).
```

means call function `double` in module `tut` with argument “10”.

The second line:
Chapter 1: Getting Started With Erlang

- `export([double/1])`. 

  says that the module `tut` contains a function called `double` which takes one argument (\( X \) in our example) and that this function can be called from outside the module `tut`. More about this later. Again note the "." at the end of the line.

  Now for a more complicated example, the factorial of a number (e.g. factorial of 4 is \( 4 \times 3 \times 2 \times 1 \)). Enter the following code in a file called `tut1.erl`.

  ```erlang
  -module(tut1).
  -export([fac/1]).

  fac(1) ->
    1;
  fac(N) ->
    N * fac(N - 1).
  ```

  Compile the file

  ```erlang
  5> c(tut1).
  {ok, tut1}
  ```

  And now calculate the factorial of 4.

  ```erlang
  6> tut1:fac(4).
  24
  ```

  The first part:

  ```erlang
  fac(1) ->
    1;
  ```

  says that the factorial of 1 is 1. Note that we end this part with a ";" which indicates that there is more of this function to come. The second part:

  ```erlang
  fac(N) ->
    N * fac(N - 1).
  ```

  says that the factorial of \( N \) is \( N \) multiplied by the factorial of \( N - 1 \). Note that this part ends with a "." saying that there are no more parts of this function.

  A function can have many arguments. Let's expand the module `tut1` with the rather stupid function to multiply two numbers:
1.2: Sequential Programming

```erlang
-module(tut1).
-export([fac/1, mult/2]).

fac(1) -> 1;
fac(N) -> N * fac(N - 1).

mult(X, Y) -> X * Y.
```

Note that we have also had to expand the `-export` line with the information that there is another function `mult` with two arguments.

Compile:

```
7> c(tut1).
{ok,tut1}
```

and try it out:

```
8> tut1:mult(3,4).
12
```

In the example above the numbers are integers and the arguments in the functions in the code, \( N \), \( X \), \( Y \) are called variables. Variables must start with a capital letter (*manual*). Examples of variable could be Number, ShoeSize, Age etc.

### 1.2.3 Atoms

Atoms are another data type in Erlang. Atoms start with a small letter (*manual*), for example: charles, centimeter, inch. Atoms are simply names, nothing else. They are not like variables which can have a value.

Enter the next program (file: `tut2.erl`) which could be useful for converting from inches to centimeters and vice versa:

```erlang
-module(tut2).
-export([convert/2]).

convert(M, inch) -> M / 2.54;

convert(N, centimeter) -> N * 2.54.
```

Compile and test:
Chapter 1: Getting Started With Erlang

9> c(tut2).
{ok,tut2}
10> tut2:convert(3, inch).
1.18110
11> tut2:convert(7, centimeter).
17.7800

Notice that I have introduced decimals (floating point numbers) without any explanation, but I guess you can cope with that.

See what happens if I enter something other than centimeter or inch in the convert function:

13> tut2:convert(3, miles).
=ERROR REPORT== 28-May-2003::18:36:27 ===
Error in process <0.25.0> with exit value: {function_clause,[[tut2,convert,[3,miles]],{erl_eval,expr,3}]
** exited: {function_clause,[[tut2,convert,[3,miles]],
{erl_eval,expr,3},
{erl_eval,exprs,4},
{shell,eval_loop,2}]} **

The two parts of the convert function are called its clauses. Here we see that “miles” is not part of either of the clauses. The Erlang system can’t match either of the clauses so we get an error message function_clause. The above output looks rather a mess, but with a little practice, you can see from it exactly where in the code the error occurred.

1.2.4 Tuples

Now the tut2 program is hardly good programming style. Consider:

tut2:convert(3, inch).

Does this mean that 3 is in inches? or that 3 is in centimeters and we want to convert it to inches? So Erlang has a way to group things together to make things more understandable. We call these tuples. Tuples are surrounded by "(" and ")".

So we can write {inch,3} to denote 3 inches and {centimeter,5} to denote 5 centimeters. Now let’s write a new program which converts centimeters to inches and vice versa. (file tut3.erl).

-module(tut3).
-export([convert_length/1]).

convert_length({centimeter, X}) ->
    {inch, X / 2.54};
convert_length({inch, Y}) ->
    {centimeter, Y * 2.54}.

Compile and test:
14> c(tut3).
{ok,tut3}
15> tut3:convert_length([inch, 5]).
{centimeter,12.7000}
16> tut3:convert_length(tut3:convert_length([inch, 5])).
{inch,5.00000}

Note on line 16 we convert 5 inches to centimeters and back again and reassuringly get back to the original value. i.e the argument to a function can be the result of another function. Pause for a moment and consider how line 16 (above) works. The argument we have given the function [inch,5] is first matched against the first head clause of convert_length i.e. convert_length([centimeter,X]) where it can be seen that [centimeter,X] does not match [inch,5] (the head is the bit before the “-”/”). This having failed, we try the head of the next clause i.e. convert_length([inch,Y]), this matches and Y get the value 5.

We have shown tuples with two parts above, but tuples can have as many parts as we want and contain any valid Erlang term. For example, to represent the temperature of various cities of the world we could write

{moscow, {c, -10}}
{cape_town, {f, 70}}
{paris, {f, 28}}

Tuples have a fixed number of things in them. We call each thing in a tuple an element. So in the tuple {moscow, {c, -10}}, element 1 is moscow and element 2 is {c, -10}. I have chosen c meaning Centigrade (or Celsius) and f meaning Fahrenheit.

1.2.5 Lists

Whereas tuples group things together, we also want to be able to represent lists of things. Lists in Erlang are surrounded by “[“ and “]”. For example a list of the temperatures of various cities in the world could be:

[moscow, {c, -10}], {cape_town, {f, 70}}, {stockholm, {c, -4}},
{paris, {f, 28}}, {london, {f, 36}}]

Note that this list was so long that it didn't fit on one line. This doesn't matter, Erlang allows line breaks at all “sensible places” but not, for example, in the middle of atoms, integers etc.

A very useful way of looking at parts of lists, is by using “|”. This is best explained by an example using the shell.

18> [First |TheRest] = [1,2,3,4,5].
[1,2,3,4,5]
19> First.
1
20> TheRest.
[2,3,4,5]
Chapter 1: Getting Started With Erlang

We use \( | \) to separate the first elements of the list from the rest of the list. (First has got value 1 and TheRest value \([2,3,4,5]\)).

Another example:

\[
\begin{align*}
21> & \quad [E_1, E_2 | R] = [1, 2, 3, 4, 5, 6, 7]. \\
& \quad [1, 2, 3, 4, 5, 6, 7] \\
22> & \quad E_1. \\
& \quad 1 \\
23> & \quad E_2. \\
& \quad 2 \\
24> & \quad R. \\
& \quad [3, 4, 5, 6, 7]
\end{align*}
\]

Here we see the use of \( | \) to get the first two elements from the list. Of course if we try to get more elements from the list than there are elements in the list we will get an error. Note also the special case of the list with no elements \([],\):

\[
\begin{align*}
25> & \quad [A, B | C] = [1, 2]. \\
& \quad [1, 2] \\
26> & \quad A. \\
& \quad 1 \\
27> & \quad B. \\
& \quad 2 \\
28> & \quad C. \\
& \quad []
\end{align*}
\]

In all the examples above, I have been using new variable names, not reusing the old ones: First, TheRest, E1, E2, R, A, B, C. The reason for this is that a variable can only be given a value once in its context (scope). I'll get back to this later, it isn't so peculiar as it sounds!

The following example shows how we find the length of a list:

- module(tut4).
- export([list_length/1]).

list_length([]) -> 0;
list_length([First | Rest]) -> 1 + list_length(Rest).

Compile (file tut4.erl) and test:

\[
\begin{align*}
29> & \quad c(tut4). \\
& \quad \{ok, tut4\} \\
30> & \quad tut4:list_length([1, 2, 3, 4, 5, 6, 7]). \\
& \quad 7
\end{align*}
\]

Explanation:
list_length([]) ->
    0;

The length of an empty list is obviously 0.

list_length([First | Rest]) ->
    1 + list_length(Rest).

The length of a list with the first element First and the remaining elements Rest is 1 + the length of Rest.

(Avanced readers only: This is not tail recursive, there is a better way to write this function).

In general we can say we use tuples where we would use “records” or “structs” in other languages and we use lists when we want to represent things which have varying sizes, (i.e. where we would use linked lists in other languages).

Erlang does not have a string date type, instead strings can be represented by lists of ASCII characters. So the list [97,98,99] is equivalent to “abc”. The Erlang shell is “clever” and guesses the what sort of list we mean and outputs it in what it thinks is the most appropriate form, for example:

31> [97,98,99].
"abc"

### 1.2.6 Standard Modules and Manual Pages

Erlang has a lot of standard modules to help you do things. For example, the module io contains a lot of functions to help you do formatted input/output. To look up information about standard modules, the command `erl -man` can be used at the operating shell or command prompt (i.e. at the same place as that where you started `erl`). Try the operating system shell command:

```
% erl -man io
ERLANG MODULE DEFINITION io(3)

MODULE
    io - Standard I/O Server Interface Functions

DESCRIPTION
    This module provides an interface to standard Erlang I/O servers. The output functions all return ok if they are suc-
...
```

If this doesn't work on your system, the documentation is included as HTML in the Erlang/OTP release, or you can read the documentation as HTML or download it as PDF from either of the sites www.erlang.se (commercial Erlang) or www.erlang.org (open source), for example for release R9B:

1.2.7 Writing Output to a Terminal

It's nice to be able to do formatted output in these examples, so the next example shows a simple way to use the `io:format` function. Of course, just like all other exported functions, you can test the `io:format` function in the shell:

32> io:format("hello world\n", []).
  hello world
  ok
33> io:format("this outputs one Erlang term: \"w\n\", [hello]).
  this outputs one Erlang term: hello
  ok
34> io:format("this outputs two Erlang terms: \"w\"\w\n\", [hello, world]).
  this outputs two Erlang terms: helloworld
  ok
35> io:format("this outputs two Erlang terms: \"w \"\w\n\", [hello, world]).
  this outputs two Erlang terms: hello world
  ok

The function `format/2` (i.e. `format` with two arguments) takes two lists. The first one is nearly always a list written between “”. This list is printed out as it stands, except that each `~w` is replaced by a term taken in order from the second list. Each `~n` is replaced by a new line. The `io:format/2` function itself returns the atom `ok` if everything goes as planned. Like other functions in Erlang, it crashes if an error occurs. This is not a fault in Erlang, it is a deliberate policy. Erlang has sophisticated mechanisms to handle errors which we will show later. As an exercise, try to make `io:format` crash, it shouldn't be difficult. But notice that although `io:format` crashes, the Erlang shell itself does not crash.

1.2.8 A Larger Example

Now for a larger example to consolidate what we have learnt so far. Assume we have a list of temperature readings from a number of cities in the world. Some of them are in Celsius (Centigrade) and some in Fahrenheit (as in the previous list). First let’s convert them all to Celsius, then let's print out the data neatly.

```erlang
%% This module is in file tut5.erl
-module(tut5).
-export([format_temps/1]).
%% Only this function is exported
format_temps([]) -> % No output for an empty list
  ok;
format_temps([City | Rest]) ->
  print_temp(convert_to_celsius(City)),
  format_temps(Rest).

convert_to_celsius([{Name, {c, Temp}}]) -> % No conversion needed
  {Name, {c, Temp}};
convert_to_celsius([{Name, {f, Temp}}]) -> % Do the conversion
  {Name, {c, (Temp - 32) * 5 / 9}}.
```

10 Getting Started with Erlang
print_temp({Name, {c, Temp}}) ->
  io:format("~-15w ~w c~n", [Name, Temp]).

36> c(tut5).
{ok, tut5}
37> tut5:format_temps([[moscow, {c, -10}], [cape_town, {f, 70}],
                       [stockholm, {c, -4}], [paris, {f, 28}],
                       [london, {f, 36}]]).
moscow -10 c
cape_town 21.1111 c
stockholm -4 c
paris -2.22222 c
london 2.22222 c
ok

Before we look at how this program works, notice that we have added a few comments to the code. A comment starts with a % character and goes on to the end of the line. Note as well that the
-export([format_temps/1]). line only includes the function format_temps/1, the other functions are
local functions, i.e. they are not visible from outside the module tut5.

Note as well that when testing the program from the shell, I had to spread the input over two lines as
the line was too long.

When we call format_temps the first time, City gets the value {moscow, {c, -10}} and Rest is the rest
of the list. So we call the function
print_temp(convert_to_celsius({moscow, {c, -10}})).

Here we see a function call as convert_to_celsius({moscow, {c, -10}}) as the argument to the
function print_temp. When we nest function calls like this we execute (evaluate) them from the inside
out. I.e. we first evaluate convert_to_celsius({moscow, {c, -10}}) which gives the value
{moscow, {c, -10}} as the temperature is already in Celsius and then we evaluate
print_temp({moscow, {c, -10}}). The function convert_to_celsius works in a similar way to the
convert_length function in the previous example.

print_temp simply calls io:format in a similar way to what has been described above. Note that ~-15w
says to print the “term” with a field length (width) of 15 and left justify it. (*manual*).

Now we call format_temps(Rest) with the rest of the list as an argument. This way of doing things is
similar to the loop constructs in other languages. (Yes, this is recursion, but don’t let that worry you).
So the same format_temps function is called again, this time City gets the value {cape_town, {f, 70}}
and we repeat the same procedure as before. We go on doing this until the list becomes empty, i.e. [],
which causes the first clause format_temps([]) to match. This simply returns (results in) the atom ok,
so the program ends.

1.2.9 Matching, Guards and Scope of Variables

It could be useful to find the maximum and minimum temperature in lists like this. Before extending
the program to do this, let’s look at functions for finding the maximum value of the elements in a list:

-module(tut6).
-export([list_max/1]).

list_max([Head|Rest]) ->
  list_max(Rest, Head).

list_max([], Res) ->
Chapter 1: Getting Started With Erlang

```
Res;
list_max([Head|Rest], Result_so_far) when Head > Result_so_far ->
    list_max(Rest, Head);
list_max([Head|Rest], Result_so_far) ->
    list_max(Rest, Result_so_far).
```

First note that we have two functions here with the same name `list_max`. However each of these takes a different number of arguments (parameters). In Erlang these are regarded as completely different functions. Where we need to distinguish between these functions we write `name/arity`, where `name` is the name of the function and `arity` is the number of arguments, in this case `list_max/1` and `list_max/2`.

This is an example where we walk through a list “carrying” a value with us, in this case `Result_so_far`. `list_max/1` simply assumes that the max value of the list is the head of the list and calls `list_max/2` with the rest of the list and the value of the head of the list, in the above this would be `list_max([2,3,4,5,7,4,3,2,1],1)`. If we tried to use `list_max/1` with an empty list or tried to use it with something which isn’t a list at all, we would cause an error. Note that the Erlang philosophy is not to handle errors of this type in the function they occur, but to do so elsewhere. More about this later.

In `list_max/2` we walk down the list and use `Head` instead of `Result_so_far` when `Head > Result_so_far`. When is a special word we use before the `-` in the function to say that we should only use this part of the function if the test which follows is true. We call tests of this type a guard. If the guard isn't true (we say the guard fails), we try the next part of the function. In this case if `Head` isn’t greater than `Result_so_far` then it must be smaller or equal to is, so we don’t need a guard on the next part of the function.

Some useful operators in guards are, `<` less than, `>` greater than, `==` equal, `>=` greater or equal, `=<` less or equal, `=/=` not equal. (*manual*).

To change the above program to one which works out the minimum value of the element in a list, all we would need to do is to write `<` instead of `>`. (But it would be wise to change the name of the function to `list_min`):

Remember that I mentioned earlier that a variable could only be given a value once in its scope? In the above we see, for example, that `Result_so_far` has been given several values. This is OK since every time we call `list_max/2` we create a new scope and one can regard the `Result_so_far` as a completely different variable in each scope.

Another way of creating and giving a variable a value is by using the match operator `=.` So if I write `M = 5`, a variable called `M` will be created and given the value 5. If, in the same scope I then write `M = 6`, I'll get an error. Try this out in the shell:

```
41> M = 5.
5
42> M = 6.
** exited: [{badmatch,6},[{erl_eval,expr,3}]] **
43> M = M + 1.
** exited: [{badmatch,6},[{erl_eval,expr,3}]] **
44> N = M + 1.
6
```
The use of the match operator is particularly useful for pulling apart Erlang terms and creating new ones.

```erlang
def(Y, [{X, Y} -> {X, [{Y, 3}]}])
def(Y, [{X, Y} -> {X, [{Y, 3}]}])
```

Here we see that \( X \) gets the value `paris` and \( Y \) `f,28`.

Of course if we try to do the same again with another city, we get an error:

```erlang
49> {X, Y} = {london, {f, 36}}.
** exited: {{badmatch,{london,{{f,36}}}},{{erl_eval,expr,3}}}
```

Variables can also be used to improve the readability of programs, for example, in the `list_max/2` function above, we could write:

```erlang
list_max([Head|Rest], Result_so_far) when Head > Result_so_far ->
    New_result_far = Head,
    list_max(Rest, New_result_far);
```

which is possibly a little clearer.

1.2.10 More About Lists

Remember that the `|` operator can be used to get the head of a list:

```erlang
50> [M1|T1] = [paris, london, rome].
[paris,london,rome]
51> M1.
paris
52> T1.
[london,rome]
```

The `|` operator can also be used to add a head to a list:

```erlang
53> L1 = [madrid | T1].
[madrid,london,rome]
54> L1.
[madrid,london,rome]
```

Now an example of this when working with lists - reversing the order of a list:
Chapter 1: Getting Started With Erlang

-module(tut8).
-export([reverse/1]).

reverse(List) ->
    reverse(List, []).

reverse([Head | Rest], Reversed_List) ->
    reverse(Rest, [Head | Reversed_List]);
reverse([], Reversed_List) ->
    Reversed_List.

56> c(tut8).
{ok,tut8}
57> tut8:reverse([1,2,3]).
[3,2,1]

Consider how Reversed_List is built. It starts as [], we then successively take off the heads of the list to be reversed and add them to the the Reversed_List, as shown in the following:

reverse([1|2,3], []) =>
    reverse([2,3], [1|[]])

reverse([2|3], [1]) =>
    reverse([3], [2|1])

reverse([3|[]], [2,1]) =>
    reverse([], [3|[2,1]])

reverse([], [3,2,1]) =>
    [3,2,1]

The module lists contains a lot of functions for manipulating lists, for example for reversing them, so before you write a list manipulating function it is a good idea to check that one isn't already written for you. (*manual*).

Now lets get back to the cities and temperatures, but take a more structured approach this time. First let's convert the whole list to Celsius as follows and test the function:

-module(tut7).
-export([[format_temps/1]].

format_temps(List_of_cities) ->
    convert_list_to_c(List_of_cities).

convert_list_to_c([{{Name, {f, F}} | Rest}] ->
    Converted_City = {Name, {c, (F -32)* 5 / 9}},
    [Converted_City | convert_list_to_c(Rest)];

convert_list_to_c([City | Rest]) ->
    [City | convert_list_to_c(Rest)];
convert_list_to_c([]) ->
    [].

58> c(tut7).
{ok, tut7}.
59> tut7:format_temps([[moscow, {c, -10}], [cape_town, {f, 70}],
                      [stockholm, {c, -4}], [paris, {f, 28}],
                      [london, {f, 36}]]).
[[moscow, {c, -10}],
 [cape_town, {c, 21.1111}],
 [stockholm, {c, -4}],
 [paris, {c, -2.22222}],
 [london, {c, 2.22222}]]

Looking at this bit by bit:

format_temps(List_of_cities) ->
    convert_list_to_c(List_of_cities, []).

Here we see that format_temps/1 calls convert_list_to_c/1. convert_list_to_c/1 takes off the head of the List_of_cities, converts it to Celsius if needed. The | operator is used to add the (maybe) converted to the converted rest of the list:

[Converted_City | convert_list_to_c(Rest)];

or

[City | convert_list_to_c(Rest)];

We go on doing this until we get to the end of the list (i.e. the list is empty:

convert_list_to_c([]) ->
    [].

Now we have converted the list, we add a function to print it:

-module(tut7).
-export([format_temps/1]).

format_temps(List_of_cities) ->
    Converted_List = convert_list_to_c(List_of_cities),
    print_temp(Converted_List).

convert_list_to_c([{{Name, {f, F}} | Rest}] ->
    Converted_City = {{Name, {c, (F -32)* 5 / 9}},
    [Converted_City | convert_list_to_c(Rest)];

convert_list_to_c([City | Rest]) ->
    [City | convert_list_to_c(Rest)];

convert_list_to_c([]) ->
    [].
We now have to add a function to find the cities with the maximum and minimum temperatures. The program below isn't the most efficient way of doing this as we walk through the list of cities four times. But it is better to first strive for clarity and correctness and to make programs efficient only if really needed.

-module(tut7).
-export([format_temps/1]).

format_temps(List_of_cities) ->
    Converted_List = convert_list_to_c(List_of_cities),
    print_temp(Converted_List),
    {Max_city, Min_city} = find_max_and_min(Converted_List),
    print_max_and_min(Max_city, Min_city).

convert_list_to_c([{Name, {f, Temp}} | Rest]) ->
    Converted_City = {Name, {c, (Temp -32)* 5 / 9}},
    [Converted_City | convert_list_to_c(Rest)];

convert_list_to_c([City | Rest]) ->
    [City | convert_list_to_c(Rest)];

convert_list_to_c([]) ->
    [].

print_temp([{{Name, {c, Temp}} | Rest}] ->
    io:format("~-15w ~w c"n", [Name, Temp]),
    print_temp(Rest);
print_temp([]) ->
    ok.

find_max_and_min([City | Rest]) ->
    find_max_and_min(Rest, City, City).

find_max_and_min([[{Name, {c, Temp}} | Rest],

60> c(tut7).
{ok, tut7}
61> tut7:format_temps([[moscow, {c, -10}], [cape_town, {f, 70}],
                      [stockholm, {c, -4}], [paris, {f, 28}], [london, {f, 36}]]).
moscow -10 c
cape_town 21.1111 c
stockholm -4 c
paris -2.22222 c
london 2.22222 c
ok

We now have to add a function to find the cities with the maximum and minimum temperatures. The program below isn't the most efficient way of doing this as we walk through the list of cities four times. But it is better to first strive for clarity and correctness and to make programs efficient only if really needed.
1.2: Sequential Programming

{Max_Name, {c, Max_Temp}},
{Min_Name, {c, Min_Temp}}) ->
if
    Temp > Max_Temp ->
        Max_City = {Name, {c, Temp}}; % Change
    true ->
        Max_City = {Max_Name, {c, Max_Temp}} % Unchanged
    end,
    if
    Temp < Min_Temp ->
        Min_City = {Name, {c, Temp}}; % Change
    true ->
        Min_City = {Min_Name, {c, Min_Temp}} % Unchanged
    end,
    find_max_and_min(Rest, Max_City, Min_City);
find_max_and_min([], Max_City, Min_City) ->
    {Max_City, Min_City}.

print_max_and_min({Max_name, {c, Max_temp}}, {Min_name, {c, Min_temp}}) ->
    io:format("Max temperature was ~w c in ~w~n", [Max_temp, Max_name]),
    io:format("Min temperature was ~w c in ~w~n", [Min_temp, Min_name]).

62> c(tut7).
{ok, tut7}
63> tut7:format_temps([["moscow", {c, -10}]], ["cape_town", {f, 70}]],
    ["stockholm", {c, -4}]], ["paris", {f, 28}]], ["london", {f, 38}]]).
moscow -10 c
cape_town 21.1111 c
stockholm -4 c
paris -2.22222 c
london 2.22222 c
Max temperature was 21.1111 c in cape_town
Min temperature was -10 c in moscow
ok

1.2.11 If and Case

The function find_max_and_min works out the maximum and minimum temperature. We have introduced a new construct here if. If works as follows:

if
    Condition 1 ->
        Action 1;
    Condition 2 ->
        Action 2;
    Condition 3 ->
        Action 3;
    Condition 4 ->
        Action 4
end
Note there is no “;” before end! Conditions are the same as guards, tests which succeed or fail. Erlang starts at the top until it finds a condition which succeeds and then it evaluates (performs) the action following the condition and ignores all other conditions and action before the end. If no condition matches, there will be a run-time failure. A condition which always succeeds is the atom, true and this is often used last in an if meaning do the action following the true if all other conditions have failed.

The following is a short program to show the workings of if.

```erlang
-module(tut9).
-export([test_if/2]).

test_if(A, B) ->
    if
        A = 5 ->
            io:format("A = 5\n", []),
            a_equals_5;
        B = 6 ->
            io:format("B = 6\n", []),
            b_equals_6;
        A == 2, B == 3 -> %i.e. A equals 2 and B equals 3
            io:format("A == 2, B == 3\n", []),
            a_equals_2_b_equals_3;
        A == 1 ; B == 7 -> %i.e. A equals 1 or B equals 7
            io:format("A == 1 ; B == 7\n", []),
            a_equals_1_or_b_equals_7
    end.
```

Testing this program gives:

```
64> c(tut9).
{ok,tut9}
65> tut9:test_if(5,33).
A = 5
a_equals_5
66> tut9:test_if(33,6).
B = 6
b_equals_6
67> tut9:test_if(2, 3).
A == 2, B == 3
a_equals_2_b_equals_3
68> tut9:test_if(1, 33).
A == 1 ; B == 7
a_equals_1_or_b_equals_7
69> tut9:test_if(33, 7).
A == 1 ; B == 7
a_equals_1_or_b_equals_7
70> tut9:test_if(33, 33).

=ERROR REPORT==== 11-Jun-2003::14:03:43 ===
Error in process <0.85.0> with exit value:
{if_clause,[[tut9,test_if,2],[erl_eval:exprs,4],[shell,eval_loop,2]]}
** exited: {if_clause,[[tut9,test_if,2],
```

18 Getting Started with Erlang
Notice that `tut9:test_if(33,33)` did not cause any condition to succeed so we got the run time error if clause. See the (*manual*) for details of the many guard tests available. case is another construct in Erlang. Recall that we wrote the convert_length function as:

```erlang
convert_length({centimeter, X}) ->
    {inch, X / 2.54};
convert_length({inch, Y}) ->
    {centimeter, Y * 2.54}.
```

We could also write the same program as:

```erlang
-module(tut10).
-export([convert_length/1]).
convert_length(Length) ->
    case Length of
        {centimeter, X} ->
            {inch, X / 2.54};
        {inch, Y} ->
            {centimeter, Y * 2.54}
    end.
```

Notice that both case and if have return values, i.e. in the above example case returned either `{inch,X/2.54}` or `{centimeter,Y*2.54}`. The behaviour of case can also be modified by using guards. An example should hopefully clarify this. The following example tells us the length of a month, given the year. We need to know the year of course, since February has 29 days in a leap year.

```erlang
-module(tut11).
-export([month_length/2]).
month_length(Year, Month) ->
    %% All years divisible by 400 are leap
    %% Years divisible by 100 are not leap (except the 400 rule above)
    %% Years divisible by 4 are leap (except the 100 rule above)
    Leap = if
        trunc(Year / 400) * 400 == Year ->
            leap;
        trunc(Year / 100) * 100 == Year ->
            not_leap;
        trunc(Year / 4) * 4 == Year ->
            leap,
    end.
leap;
true ->
    not_leap
end,
case Month of
    sep -> 30;
    apr -> 30;
    jun -> 30;
    nov -> 30;
    feb when Leap == leap -> 29;
    feb -> 28;
    jan -> 31;
    mar -> 31;
    may -> 31;
    jul -> 31;
    aug -> 31;
    oct -> 31;
    dec -> 31
end.

74> c(tut11).
    {ok,tut11}
    29
    28
77> tut11:month_length(1947, aug).
    31

1.2.12 Built In Functions (BIFs)

Built in functions BIFs are functions which for some reason is built in to the Erlang virtual machine. BIFs often implement functionality that is impossible to implement in Erlang or is to inefficient to implement in Erlang. Some BIFs can be called by use of the function name only but they are by default belonging to the erlang module so for example the call to the BIF `trunc` below is equivalent with a call to `erlang:trunc`.

As you can see, we first find out if a year is leap or not. If a year is divisible by 400, it is a leap year. To find this out we first divide the year by 400 and use the built in function `trunc` (more later) to cut off any decimals. We then multiply by 400 again and see if we get back the same value. For example, year 2004:

\[
\begin{align*}
    2004 / 400 &= 5.01 \\
    \text{trunc}(5.01) &= 5 \\
    5 \times 400 &= 2000
\end{align*}
\]

and we can see that we got back 2000 which is not the same as 2004, so 2004 isn't divisible by 400. Year 2000:

\[
\begin{align*}
    2000 / 400 &= 5.0 \\
    \text{trunc}(5.0) &= 5 \\
    5 \times 400 &= 2000
\end{align*}
\]
so we have a leap year. The next two tests if the year is divisible by 100 or 4 are done in the same way. The first if returns leap or not_leap which lands up in the variable Leap. We use this variable in the guard for feb in the following case which tells us how long the month is. This example showed the use of trunc, an easier way would be to use the Erlang operator rem which gives the remainder after division. For example:

\[
2 \times 2004 \text{ rem } 400. \\
4
\]

so instead of writing

\[
\text{trunc(Year / 400) * 400 == Year -> leap;}
\]

we could write

\[
\text{Year rem 400 == 0 -> leap;}
\]

There are many other built in functions (BIF) such as trunc. Only a few built in functions can be used in guards, and you cannot use functions you have defined yourself in guards. (*manual*) (Aside for advanced readers: This is to ensure that guards don't have side effects). Let's play with a few of these functions in the shell:

\[
78 \times \text{trunc(5.6).} \\
5
\]
\[
79 \times \text{round(5.6).} \\
6
\]
\[
80 \times \text{length([a,b,c,d]).} \\
4
\]
\[
81 \times \text{float(5).} \\
5.00000
\]
\[
82 \times \text{is_atom(hello).} \\
true
\]
\[
83 \times \text{is_atom("hello").} \\
false
\]
\[
84 \times \text{is_tuple([paris, {c, 30}]).} \\
true
\]
\[
85 \times \text{is_tuple([paris, {c, 30}]).} \\
false
\]

All the above can be used in guards. Now for some which can't be used in guards:

\[
87 \times \text{atom_to_list(hello).} \\
"hello"
\]
\[
88 \times \text{list_to_atom("goodbye").} \\
goodbye
\]
\[
89 \times \text{integer_to_list(22).} \\
"22"
\]

The 3 BIFs above do conversions which would be difficult (or impossible) to do in Erlang.
Chapter 1: Getting Started With Erlang

1.2.13 Higher Order Functions (Funs)

Erlang, like most modern functional programming languages, has higher order functions. We start with an example using the shell:

```
90> Xf = fun(X) -> X * 2 end.
#Fun<erl_eval.5.123085357>
91> Xf(5).
10
```

What we have done here is to define a function which doubles the value of number and assign this function to a variable. Thus \( Xf(5) \) returned the value 10. Two useful functions when working with lists are `foreach` and `map`, which are defined as follows:

```
foreach(Fun, [First|Rest]) ->
    Fun(First),
    foreach(Fun, Rest);
foreach(Fun, []) ->
    ok.

map(Fun, [First|Rest]) ->
    [Fun(First)|map(Fun,Rest)];
map(Fun, []) ->
    [].
```

These two functions are provided in the standard module `lists`. `foreach` takes a list and applies a fun to every element in the list, `map` creates a new list by applying a fun to every element in a list. Going back to the shell, we start by using `map` and a fun to add 3 to every element of a list:

```
92> Add3 = fun(X) -> X + 3 end.
#Fun<erl_eval.5.123085357>
93> lists:map(Add3, [1,2,3]).
[4,5,6]
```

Now let's print out the temperatures in a list of cities (yet again):

```
95> Print_City = fun({City, {X, Temp}}) -> io:format("~-15w ~w ~w\n", [City, X, Temp]) end.
#Fun<erl_eval.5.123085357>
96> lists:foreach(Print_City, [[moscow, {c, -10}], [cape_town, {f, 70}], [stockholm, {c, -4}], [paris, {f, 28}], [london, {f, 36}]]).
moscow c -10
cape_town f 70
stockholm c -4
paris f 28
london f 36
ok
```

We will now define a fun which can be used to go through a list of cities and temperatures and transform them all to Celsius.
1.2: Sequential Programming

-module(tut13).
-export([convert_list_to_c/1]).

convert_to_c({Name, {f, Temp}}) ->
    {Name, {c, trunc((Temp - 32) * 5 / 9)});
convert_to_c({Name, {c, Temp}}) ->
    {Name, {c, Temp}}.

convert_list_to_c(List) ->
    lists:map(fun convert_to_c/1, List).

98> tut13:convert_list_to_c([[moscow, {c, -10}], {cape_town, {f, 70}},
                              {stockholm, {c, -4}], {paris, {f, 28}], {london, {f, 36}}]).
[[moscow,{c,-10}],
 {cape_town,{c,21]},

The convert_to_c function is the same as before, but we use it as a fun:

lists:map(fun convert_to_c/1, List)

When we use a function defined elsewhere as a fun we can refer to it as Function/Arity (remember that Arity = number of arguments). So in the map call we write lists:map(fun convert_to_c/1, List). As you can see convert_list_to_c becomes much shorter and easier to understand.

The standard module lists also contains a function sort(Fun, List) where Fun is a fun with two arguments. This fun should return true if the the first argument is less than the second argument, or else false. We add sorting to the convert_list_to_c:

-module(tut13).
-export([convert_list_to_c/1]).

convert_to_c({Name, {f, Temp}}) ->
    {Name, {c, trunc((Temp - 32) * 5 / 9)});
convert_to_c({Name, {c, Temp}}) ->
    {Name, {c, Temp}}.

convert_list_to_c(List) ->
    New_list = lists:map(fun convert_to_c/1, List),
    lists:sort(fun(fun(_, {c, Temp1}), (_, {c, Temp2}) ->
        Temp1 < Temp2 end, New_list).

99> c(tut13).
{ok,tut13}
100> tut13:convert_list_to_c([[moscow, {c, -10}], {cape_town, {f, 70}},
                               {stockholm, {c, -4}], {paris, {f, 28}], {london, {f, 36}}]).
[[moscow,{c,-10}],
 {stockholm,{c,-4}],
In sort we use the fun:

\[
\text{fun}(_{\_}, \{c, \text{Temp1}\}_{\_}, \{c, \text{Temp2}\}_{\_}) \rightarrow \text{Temp1} < \text{Temp2} \text{ end,}
\]

Here we introduce the concept of an anonymous variable "\_". This is simply shorthand for a variable which is going to get a value, but we will ignore the value. This can be used anywhere suitable, not just in fun's Temp1 < Temp2 returns true if Temp1 is less than Temp2.

### 1.3 Concurrent Programming

#### 1.3.1 Processes

One of the main reasons for using Erlang instead of other functional languages is Erlang's ability to handle concurrency and distributed programming. By concurrency we mean programs which can handle several threads of execution at the same time. For example, modern operating systems would allow you to use a word processor, a spreadsheet, a mail client and a print job all running at the same time. Of course each processor (CPU) in the system is probably only handling one thread (or job) at a time, but it swaps between the jobs a such a rate that it gives the illusion of running them all at the same time. It is easy to create parallel threads of execution in an Erlang program and it is easy to allow these threads to communicate with each other. In Erlang we call each thread of execution a process.

(Aside: the term “process” is usually used when the threads of execution share no data with each other and the term “thread” when they share data in some way. Threads of execution in Erlang share no data, that’s why we call them processes).

The Erlang BIF \texttt{spawn} is used to create a new process: \texttt{spawn(Module, Exported\_Function, List\_of\_Arguments)}. Consider the following module:

\begin{verbatim}
-module(tut14).
-export([[start/0, say\_something/2]]).

say\_something(What, 0) ->
    done;
say\_something(What, Times) ->
    io:format("p\n", [What]),
    say\_something(What, Times - 1).

start() ->
    spawn(tut14, say\_something, [hello, 3]),
    spawn(tut14, say\_something, [goodbye, 3]).
\end{verbatim}
We can see that function say_something writes its first argument the number of times specified by second argument. Now look at the function start. It starts two Erlang processes, one which writes “hello” three times and one which writes “goodbye” three times. Both of these processes use the function say_something. Note that a function used in this way by spawn to start a process must be exported from the module (i.e. in the -export at the start of the module).

Notice that it didn’t write “hello” three times and then “goodbye” three times, but the first process wrote a “hello”, the second a “goodbye”, the first another “hello” and so forth. But where did the \textless 0.63.0\textgreater come from? The return value of a function is of course the return value of the last “thing” in the function. The last thing in the function start is

\texttt{spawn(tut14, say\_something, \{goodbye, 3\}).}

\texttt{spawn} returns a process identifier, or pid, which uniquely identifies the process. So \textless 0.63.0\textgreater is the pid of the \texttt{spawn} function call above. We will see how to use pids in the next example.

Note as well that we have used \texttt{~p} instead of \texttt{~w} in \texttt{io:format}. To quote the manual: “\texttt{~p} Writes the data with standard syntax in the same way as \texttt{~w}, but breaks terms whose printed representation is longer than one line into many lines and indents each line sensibly. It also tries to detect lists of printable characters and to output these as strings”.

### 1.3.2 Message Passing

In the following example we create two processes which send messages to each other a number of times.

\texttt{-module(tut15).}

\texttt{-exports([start/0, ping/2, pong/0]).}

\texttt{ping(0, Pong\_PID) ->}

\texttt{ Pong\_PID ! finished,}

\texttt{ io:format("ping finished\n", [])};
ping(N, Pong_PID) ->
    Pong_PID ! {ping, self()},
    receive
        pong ->
            io:format("Ping received pong~n", [])
        end, ping(N - 1, Pong_PID).

pong() ->
    receive
        finished ->
            io:format("Pong finished~n", []);
        {ping, Ping_PID} ->
            io:format("Pong received ping~n", []), Ping_PID ! pong, pong()
    end.

start() ->
    Pong_PID = spawn(tut15, pong, []),
    spawn(tut15, ping, [3, Pong_PID]).

1> c(tut15).
{ok,tut15}
2> tut15:start().
<0.36.0>
Pong received ping
Ping received pong
Pong received ping
Ping received pong
Pong received ping
Ping received pong
ping finished
Pong finished

The function start first creates a process, let's call it "pong":

Pong_PID = spawn(tut15, pong, [])

This process executes tut15:pong(). Pong_PID is the process identity of the "pong" process. The function start now creates another process "ping".

spawn(tut15, ping, [3, Pong_PID]),

this process executes

tut15:ping(3, Pong_PID)

<0.36.0> is the return value from the start function.

The process "pong" now does:
receive 
  finished ->
    io:format("Pong finished~n", []);
  {ping, Ping_PID} ->
    io:format("Pong received ping~n", []),
    Ping_PID ! pong,
    pong()
end.

The `receive` construct is used to allow processes to wait for messages from other processes. It has the format:

```
receive
  pattern1 ->
    actions1;
  pattern2 ->
    actions2;
  ...
  patternN
    actionsN
end.
```

Note: no ";" before the `end`.

Messages between Erlang processes are simply valid Erlang terms. I.e. they can be lists, tuples, integers, atoms, pids etc.

Each process has its own input queue for messages it receives. New messages received are put at the end of the queue. When a process executes a `receive`, the first message in the queue is matched against the first pattern in the `receive`, if this matches, the message is removed from the queue and the actions corresponding to the pattern are executed. However, if the first pattern does not match, the second pattern is tested, if this matches the message is removed from the queue and the actions corresponding to the second pattern are executed. If the second pattern does not match the third is tried and so on until there are no more pattern to test. If there are no more patterns to test, the first message is kept in the queue and we try the second message instead. If this matches any pattern, the appropriate actions are executed and the second message is removed from the queue (keeping the first message and any other messages in the queue). If the second message does not match we try the third message and so on until we reach the end of the queue. If we reach the end of the queue, the process blocks (stops execution) and waits until a new message is received and this procedure is repeated.

Of course the Erlang implementation is "clever" and minimizes the number of times each message is tested against the patterns in each `receive`.

Now back to the ping pong example.

"Pong" is waiting for messages. If the atom `finished` is received, "pong" writes "Pong finished" to the output and as it has nothing more to do, terminates. If it receives a message with the format:

```
{ping, Ping_PID}
```

it writes "Pong received ping" to the output and sends the atom `pong` to the process "ping":

```
Ping_PID ! pong
```
Note how the operator “!” is used to send messages. The syntax of “!” is:

Pid ! Message

I.e. Message (any Erlang term) is sent to the process with identity Pid.

After sending the message pong, to the process “ping”, “pong” calls the pong function again, which causes it to get back to the receive again and wait for another message. Now let's look at the process “ping”. Recall that it was started by executing:

tut15:ping(3, Pong_PID)

Looking at the function ping/2 we see that the second clause of ping/2 is executed since the value of the first argument is 3 (not 0) (first clause head is ping(0,Pong_PID), second clause head is ping(N,Pong_PID), so N becomes 3).

The second clause sends a message to “pong”:

Pong_PID ! {ping, self()},

self() returns the pid of the process which executes self(), in this case the pid of “ping”. (Recall the code for “pong”, this will land up in the variable Ping_PID in the receive previously explained).

“Ping” now waits for a reply from “pong”:

receive
    pong ->
        io:format("Ping received pong\n", [])
end,

and writes “Ping received pong” when this reply arrives, after which “ping” calls the ping function again.

ping(N - 1, Pong_PID)

N-1 causes the first argument to be decremented until it becomes 0. When this occurs, the first clause of ping/2 will be executed:

ping(0, Pong_PID) ->
    Pong_PID ! finished,
    io:format("ping finished\n", []);

The atom finished is sent to “pong” (causing it to terminate as described above) and “ping finished” is written to the output. “Ping” then itself terminates as it has nothing left to do.
1.3.3 Registered Process Names

In the above example, we first created “pong” so as to be able to give the identity of “pong” when we started “ping”, i.e. in some way “ping” must be able to know the identity of “pong” in order to be able to send a message to it. Sometimes processes which need to know each others identities are started completely independently of each other. Erlang thus provides a mechanism for processes to be given names so that these names can be used as identities instead of pids. This is done by using the `register` BIF:

```erlang
register(some_atom, Pid)
```

We will now re-write the ping pong example using this and giving the name `pong` to the “pong” process:

```erlang
-module(tut16).
-export([start/0, ping/1, pong/0]).

ping(0) ->
    pong ! finished,
    io:format("ping finished\n", []);

ping(N) ->
    pong ! {ping, self()},
    receive
        pong ->
            io:format("Ping received pong\n", [])
    end,
    ping(N - 1).

pong() ->
    receive
        finished ->
            io:format("Pong finished\n", []);
        {ping, Ping_PID} ->
            io:format("Pong received ping\n", []),
            Ping_PID ! pong,
            pong()
    end.

start() ->
    register(pong, spawn(tut16, pong, [])),
    spawn(tut16, ping, [3]).
```

```
c(tut16).
{ok, tut16}
3> tut16:start().
<0.38.0>
Pong received ping
Ping received pong
Pong received ping
Ping received pong
Pong received ping
Ping received pong
```
In the start/0 function,

register(pong, spawn(tut16, pong, [])),

both spawns the "pong" process and gives it the name pong. In the "ping" process we can now send messages to pong by:

pong ! {ping, self()},

so that ping/2 now becomes ping/1 as we don't have to use the argument Pong_PID.

1.3.4 Distributed Programming

Now let's re-write the ping pong program with "ping" and "pong" on different computers. Before we do this, there are a few things we need to set up to get this to work. The distributed Erlang implementation provides a basic security mechanism to prevent unauthorized access to an Erlang system on another computer (*manual*). Erlang systems which talk to each other must have the same magic cookie. The easiest way to achieve this is by having a file called .erlang.cookie in your home directory on all machines which you are going to run Erlang systems communicating with each other (on Windows systems the home directory is the directory where pointed to by the $HOME environment variable - you may need to set this. On Linux or Unix you can safely ignore this and simply create a file called .erlang.cookie in the directory you get to after executing the command cd without any argument). The .erlang.cookie file should contain on line with the same atom. For example on Linux or Unix in the OS shell:

```
$ cd
$ cat > .erlang.cookie
   this_is_very_secret
$ chmod 400 .erlang.cookie
```

The chmod above make the .erlang.cookie file accessible only by the owner of the file. This is a requirement.

When you start an Erlang system which is going to talk to other Erlang systems, you must give it a name, eg:

```
erl -sname my_name
```

We will see more details of this later (*manual*). If you want to experiment with distributed Erlang, but you only have one computer to work on, you can start two separate Erlang systems on the same computer but give them different names. Each Erlang system running on a computer is called an Erlang node.

(Note: erl -sname assumes that all nodes are in the same IP domain and we can use only the first component of the IP address, if we want to use nodes in different domains we use -name instead, but then all IP address must be given in full (*manual*).)

Here is the ping pong example modified to run on two separate nodes:
-module(tut17).

-export([start_ping/1, start_pong/0, ping/2, pong/0]).

ping(0, Pong_Node) ->
    {pong, Pong_Node} ! finished,
    io:format("ping finished\n", []);

ping(N, Pong_Node) ->
    {pong, Pong_Node} ! {ping, self()},
    receive
        pong ->
            io:format("Ping received pong\n", [])
    end,
    ping(N - 1, Pong_Node).

pong() ->
    receive
        finished ->
            io:format("Pong finished\n", []);
        {ping, Ping_PID} ->
            io:format("Pong received ping\n", []),
            Ping_PID ! pong,
            pong()
    end.

start_pong() ->
    register(pong, spawn(tut17, pong, [])).

start_ping(Pong_Node) ->
    spawn(tut17, ping, [3, Pong_Node]).

Let us assume we have two computers called gollum and kosken. We will start a node on kosken called ping and then a node on gollum called pong.

On kosken (on a Linux/Unix system):

kosken> erl -sname ping
Erlang (BEAM) emulator version 5.2.3.7 [hipe] [threads:0]

Eshell V5.2.3.7 (abort with ^G)
(ping@kosken)1>

On gollum:

gollum> erl -sname pong
Erlang (BEAM) emulator version 5.2.3.7 [hipe] [threads:0]

Eshell V5.2.3.7 (abort with ^G)
(pong@gollum)1>
Now we start the “pong” process on gollum:

```
(pong@gollum)1> tut17:start_pong().
true
```

and start the “ping” process on kosken (from the code above you will see that a parameter of the `start` function is the node name of the Erlang system where “pong” is running):

```
(ping@kosken)1> tut17:start_ping(pong@gollum).
<0.37.0>
Ping received pong
Ping received pong
Ping received pong
ping finished
```

Here we see that the ping pong program has run, on the “pong” side we see:

```
(pong@gollum)2> Pong received ping
Pong received ping
Pong received ping
Pong finished
(pong@gollum)2>
```

Looking at the `tut17` code we see that the `pong` function itself is unchanged, the lines:

```
{ping, Ping_PID} ->
    io:format("Pong received ping\n", []),
    Ping_PID ! pong,
```

work in the same way irrespective of on which node the “ping” process is executing. Thus Erlang pids contain information about where the process executes so if you know the pid of a process, the “!” operator can be used to send it a message if the process is on the same node or on a different node.

A difference is how we send messages to a registered process on another node:

```
{pong, Pong_Node} ! {ping, self()},
```

We use a tuple `{registered_name, node_name}` instead of just the `registered_name`.

In the previous example, we started “ping” and “pong” from the shells of two separate Erlang nodes. `spawn` can also be used to start processes in other nodes. The next example is the ping pong program, yet again, but this time we will start “ping” in another node:
-module(tut18).

-export([start/1, ping/2, pong/0]).

ping(N, Pong_Node) ->
    {pong, Pong_Node} ! finished,
    io:format("ping finished\n", []).

ping(N, Pong_Node) ->
    {pong, Pong_Node} ! {ping, self()},
    receive
        pong ->
            io:format("Ping received pong\n", [])
        end,
    ping(N - 1, Pong_Node).

pong() ->
    receive
        finished ->
            io:format("Pong finished\n", []);
        {ping, Ping_PID} ->
            io:format("Pong received ping\n", []),
            Ping_PID ! pong,
            pong()
    end.

start(Ping_Node) ->
    register(pong, spawn(tut18, pong, [])),
    spawn(Ping_Node, tut18, ping, [3, node()]).

Assuming an Erlang system called ping (but not the “ping” process) has already been started on kosken, then on gollum we do:

```
(pong@gollum)1> tut18:start(ping@kosken).
<3934.39.0>
Pong received ping
Ping received pong
Pong received ping
Ping received pong
Pong received ping
Ping received pong
Pong finished
ping finished
```

Notice we get all the output on gollum. This is because the io system finds out where the process is spawned from and sends all output there.

### 1.3.5 A Larger Example

Now for a larger example. We will make an extremely simple “messenger”. The messenger is a program which allows users to log in on different nodes and send simple messages to each other.
Chapter 1: Getting Started With Erlang

Before we start, let’s note the following:

- This example will just show the message passing logic no attempt at all has been made to provide a nice graphical user interface - this can of course also be done in Erlang - but that’s another tutorial.
- This sort of problem can be solved more easily if you use the facilities in OTP, which will also provide methods for updating code on the fly etc. But again, that’s another tutorial.
- The first program we write will contain some inadequacies as regards handling of nodes which disappear, we will correct these in a later version of the program.

We will set up the messenger by allowing “clients” to connect to a central server and say who and where they are. I.e. a user won’t need to know the name of the Erlang node where another user is located to send a message.

File `messenger.erl`:

```erlang
%%% Message passing utility.
%%% User interface:
%%% logon(Name)
%%% One user at a time can log in from each Erlang node in the system messenger: and choose a suitable Name. If the Name is already logged in at another node or if someone else is already logged in at the same node, login will be rejected with a suitable error message.
%%% logoff()
%%% Logs off anybody at at node
%%% message(ToName, Message)
%%% sends Message to ToName. Error messages if the user of this function is not logged on or if ToName is not logged on at any node.
%%% One node in the network of Erlang nodes runs a server which maintains data about the logged on users. The server is registered as "messenger"
%%% Each node where there is a user logged on runs a client process registered as "mess_client"
%%% Protocol between the client processes and the server
%%%-----------------------------------------------
%%% To server: {ClientPid, logon, UserName}
%%% Reply {messenger, stop, user_exists_at_other_node} stops the client
%%% Reply {messenger, logged_on} logon was successful
%%% To server: {ClientPid, logoff}
%%% Reply: {messenger, logged_off}
%%% To server: {ClientPid, logoff}
%%% Reply: no reply
%%% To server: {ClientPid, message_to, ToName, Message} send a message
%%% Reply: {messenger, stop, you_are_not_logged_on} stops the client
%%% Reply: {messenger, receiver_not_found} no user with this name logged on
%%% Reply: {messenger, sent} Message has been sent (but no guarantee)
```
1.3: Concurrent Programming

%% To client: \{message_from, Name, Message\},
%% Protocol between the "commands" and the client
%% ----------------------------------------------
%% Started: messenger:client\(\text{Server\_Node, Name}\)
%% To client: logoff
%% To client: \{message_to, ToName, Message\}
%% Configuration: change the server_node() function to return the
%% name of the node where the messenger server runs

-module(messenger).
-export([start_server/0, server/1, logon/1, logoff/0, message/2, client/2]).

%% Start the server
start_server() ->
    register(messenger, spawn(messenger, server, [[]])).

%% This is the server process for the "messenger"
%% the user list has the format \{{Client\_Pid\_1, Name\_1}, \{{Client\_Pid\_2, Name\_2}, \ldots\} server(User\_List) ->
    receive
      \{From, logon, Name\} ->
        New\_User\_List = server\_logon(From, Name, User\_List),
        server(New\_User\_List);
      \{From, logoff\} ->
        New\_User\_List = server\_logoff(From, User\_List),
        server(New\_User\_List);
      \{From, message\_to, To, Message\} ->
        server\_transfer(From, To, Message, User\_List),
        io:format("list is now: ~p\n\n", [User\_List]),
        server(User\_List)
    end.

%% Start the server
start_server() ->
    register(messenger, spawn(messenger, server, [[]])).

%% Server adds a new user to the user list
server\_logon(From, Name, User\_List) ->
    %% check if logged on anywhere else
    case lists:keymember(Name, 2, User\_List) of
      true ->
        From ! \{messenger, stop, user\_exists\_at\_other\_node\}, \%reject logon
        User\_List;
      false ->
        From ! \{messenger, logged\_on\},
        [(From, Name) | User\_List] \%add user to the list
    end.

Getting Started with Erlang
%%% Server deletes a user from the user list
server_logoff(From, User_List) ->
    lists:delete(From, 1, User_List).

%%% Server transfers a message between users
server_transfer(From, To, Message, User_List) ->
    %% check that the user is logged on and who he is
    case lists:keysearch(From, 1, User_List) of
        false ->
            From ! {messenger, stop, you_are_not_logged_on};
        {value, {From, Name}} ->
            server_transfer(From, Name, To, Message, User_List)
    end.

%%% If the user exists, send the message
server_transfer(From, Name, To, Message, User_List) ->
    %% Find the receiver and send the message
    case lists:keysearch(To, 2, User_List) of
        false ->
            From ! {messenger, receiver_not_found};
        {value, {ToPid, To}} ->
            ToPid ! {message_from, Name, Message},
            From ! {messenger, sent}
    end.

%%% User Commands
logon(Name) ->
    case whereis(mess_client) of
        undefined ->
            register(mess_client,
                spawn(messenger, client, [server_node(), Name]));
        _ -> already_logged_on
    end.

logoff() ->
    mess_client ! logoff.

message(ToName, Message) ->
    case whereis(mess_client) of
        undefined ->
            not_logged_on;
        _ -> mess_client ! {message_to, ToName, Message},
            ok
    end.

%%% The client process which runs on each server node
client(Server_Node, Name) ->
    {messenger, Server_Node} ! {self(), logon, Name},
    await_result(),
    client(Server_Node).
1.3: Concurrent Programming

client(Server_Node) ->
    receive
        logoff ->
            {messenger, Server_Node} ! {self(), logoff},
            exit(normal);
        {message_to, ToName, Message} ->
            {messenger, Server_Node} ! {self(), message_to, ToName, Message},
            await_result();
        {message_from, FromName, Message} ->
            io:format("Message from ~p: "p"n", [FromName, Message])
    end,
    client(Server_Node).

%%% wait for a response from the server
await_result() ->
    receive
        {messenger, stop, Why} -> % Stop the client
            io:format("~p~n", [Why]),
            exit(normal);
        {messenger, What} -> % Normal response
            io:format("~p~n", [What])
    end.

To use this program you need to:

- configure the server_node() function
- copy the compiled code (messenger.beam) to the directory on each computer where you start Erlang.

In the following example of use of this program, I have started nodes on four different computers, but if you don’t have that many machines available on your network, you could start up several nodes on the same machine.

We start up four Erlang nodes, messenger@super, c1@bilbo, c2@kosken, c3@gollum.
First we start up the server at messenger@super:

(messenger@super)i> messenger:start_server().
true

Now Peter logs on at c1@bilbo:

(c1@bilbo)i> messenger:logon(peter).
true
logged_on

James logs on at c2@kosken:

(c2@kosken)i> messenger:logon(james).
true
logged_on

Getting Started with Erlang 37
and Fred logs on at c3@gollum:

```erlang
(c3@gollum)1> messenger:logon(fred).
true
logged on
```

Now Peter sends Fred a message:

```erlang
(c1@bilbo)2> messenger:message(fred, "hello").
ok
sent
```

And Fred receives the message and sends a message to Peter and logs off:

```erlang
Message from peter: "hello"
(c3@gollum)2> messenger:message(peter, "go away, I'm busy").
ok
sent
(c3@gollum)3> messenger:logoff().
logoff
```

James now tries to send a message to Fred:

```erlang
(c2@kosken)2> messenger:message(fred, "peter doesn't like you").
ok
receiver_not_found
```

But this fails as Fred has already logged off.

First let’s look at some of the new concepts we have introduced.

There are two versions of the server_transfer function, one with four arguments (server_transfer/4) and one with five (server_transfer/5). These are regarded by Erlang as two separate functions.

Note how we write the server function so that it calls itself, server(UserList) and thus creates a loop. The Erlang compiler is “clever” and optimizes the code so that this really is a sort of loop and not a proper function call. But this only works if there is no code after the call, otherwise the compiler will expect the call to return and make a proper function call. This would result in the process getting bigger and bigger for every loop.

We use functions in the lists module. This is a very useful module and a study of the manual page is recommended (erl -man lists). lists:keymember(Key,Position,Lists) looks through a list of tuples and looks at Position in each tuple to see if it is the same as Key. The first element is position 1. If it finds a tuple where the element at Position is the same as Key, it returns true, otherwise false.

```erlang
3> lists:keymember(a, 2, [[x,y,z],[b,b,b],[b,a,c],[q,r,s]]).
true
4> lists:keymember(p, 2, [[x,y,z],[b,b,b],[b,a,c],[q,r,s]]).
false
```
lists:keydelete works in the same way but deletes the first tuple found (if any) and returns the remaining list:

```erlang
5> lists:keydelete(a, 2, [{x,y,z},{b,b,b},{b,a,c},{q,r,s}]).
[{x,y,z},{b,b,b},{q,r,s}]
```

lists:keysearch is like lists:keymember, but it returns {value, Tuple_found} or the atom false. There are a lot more very useful functions in the lists module.

An Erlang process will (conceptually) run until it does a receive and there is no message which it wants to receive in the message queue. I say “conceptually” because the Erlang system shares the CPU time between the active processes in the system.

A process terminates when there is nothing more for it to do, i.e. the last function it calls simply returns and doesn’t call another function. Another way for a process to terminate is for it to call exit/1. The argument to exit/1 has a special meaning which we will look at later. In this example we will do exit(normal) which has the same effect as a process running out of functions to call.

The BIF whereis(RegisteredName) checks if a registered process of name RegisteredName exists and return the pid of the process if it does exist or the atom undefined if it does not.

You should by now be able to understand most of the code above so I’ll just go through one case: a message is sent from one user to another.

The first user “sends” the message in the example above by:

```erlang
messenger:message(fred, "hello")
```

After testing that the client process exists:

```erlang
whereis(mess_client)
```

and a message is sent to mess_client:

```erlang
mess_client ! {message_to, fred, "hello"}
```

The client sends the message to the server by:

```erlang
{messenger, messenger@super} ! {self(), message_to, fred, "hello"},
```

and waits for a reply from the server. The server receives this message and calls:

```erlang
server_transfer(From, fred, "hello", User_List),
```

which checks that the pid From is in the User_List:

```erlang
lists:keysearch(From, 1, User_List)
```

If keysearch returns the atom false, some sort of error has occurred and the server sends back the message:

```erlang
From ! {messenger, stop, you_are_not_logged_on}
```
which is received by the client which in turn does exit(normal) and terminates. If keysearch returns
{value,From,Name} we know that the user is logged on and is his name (peter) is in variable Name. We
now call:

server_transfer(From, peter, fred, "hello", User_List)

Note that as this is server_transfer/5 it is not the same as the previous function server_transfer/4. We
do another keysearch on User_List to find the pid of the client corresponding to fred:

lists:keyword(fred, 2, User_List)

This time we use argument 2 which is the second element in the tuple. If this returns the atom false
we know that fred is not logged on and we send the message:

From ! {messenger, receiver_not_found};

which is received by the client, if keysearch returns:

{value, {ToPid, fred}}

we send the message:

ToPid ! {message_from, peter, "hello"},

to fred's client and the message:

From ! {messenger, sent}

to peter's client.

Fred's client receives the message and prints it:

{message_from, peter, "hello"} ->
     io:format("Message from ~p: ~p

and peter's client receives the message in the await_result function.

1.4 Robustness

There are several things which are wrong with the messenger example [page 34] from the previous
chapter. For example if a node where a user is logged on goes down without doing a log off, the user
will remain in the server's User_List but the client will disappear thus making it impossible for the user
to log on again as the server thinks the user already logged on.

Or what happens if the server goes down in the middle of sending a message leaving the sending client
hanging for ever in the await_result function?
1.4.1 Timeouts

Before improving the messenger program we will look into some general principles, using the ping pong program as an example. Recall that when "ping" finishes, it tells "pong" that it has done so by sending the atom `finished` as a message to "pong" so that "pong" could also finish. Another way to let "pong" finish, is to make "pong" exit if it does not receive a message from ping within a certain time, this can be done by adding a timeout to pong as shown in the following example:

```erlang
-module(tut19).
-export([start_ping/1, start_pong/0, ping/2, pong/0]).
ping(0, Pong_Node) ->
    io:format("ping finished\n", []);
ping(N, Pong_Node) ->
    {pong, Pong_Node} ! {ping, self()},
    receive
    pong ->
        io:format("Ping received pong \n", [])
    end,
    ping(N - 1, Pong_Node).
pong() ->
    receive
    {ping, Ping_PID} ->
        io:format("Pong received ping\n", []),
        Ping_PID ! pong,
        pong()
    after 5000 ->
        io:format("Pong timed out\n", [])
    end.
start_pong() ->
    register(pong, spawn(tut19, pong, [])).
start_ping(Pong.Node) ->
    spawn(tut19, ping, [3, Pong.Node]).
```

After we have compiled this and copied the tut19.beam file to the necessary directories:

On (pong@kosken):

```
(pong@kosken)1> tut19:start_pong().
true
Pong received ping
Pong received ping
Pong received ping
Pong timed out
```

On (ping@gollum):
Chapter 1: Getting Started With Erlang

```erlang
(ping@gollum)1> tut19:start_ping(pong@kosken).
<0.36.0>
Ping received pong
Ping received pong
Ping received pong
ping finished

(The timeout is set in:

pong() ->
    receive
        {ping, Ping_PID} ->
            io:format("Pong received ping~n", []),
            Ping_PID ! pong,
            pong()
    after 5000 ->
            io:format("Pong timed out~n", [])
    end.

We start the timeout (after 5000) when we enter receive. The timeout is canceled if
{ping, Ping_PID} is received. If {ping, Ping_PID} is not received, the actions following the timeout
will be done after 5000 milliseconds after must be last in the receive, i.e. preceded by all other
message reception specifications in the receive. Of course we could also call a function which returned
an integer for the timeout:

after pong_timeout() ->

In general, there are better ways than using timeouts to supervise parts of a distributed Erlang system.
Timeouts are usually appropriate to supervise external events, for example if you have expected a
message from some external system within a specified time. For example, we could use a timeout to log
a user out of the messenger system if they have not accessed it, for example, in ten minutes.

1.4.2 Error Handling

Before we go into details of the supervision and error handling in an Erlang system, we need see how
Erlang processes terminate, or in Erlang terminology, exit.
A process which executes exit(normal) or simply runs out of things to do has a normal exit.
A process which encounters a runtime error (e.g. divide by zero, bad match, trying to call a function
which doesn't exist etc) exits with an error, i.e. has an abnormal exit. A process which executes
exit(Reason) (*manual*) where Reason is any Erlang term except the atom normal, also has an
abnormal exit.
An Erlang process can set up links to other Erlang processes. If a process calls link(Other_Pid)
(*manual*) it sets up a bidirectional link between itself and the process called Other_Pid. When a
process terminates its sends something called a signal to all the processes it has links to.
The signal carries information about the pid it was sent from and the exit reason.
The default behaviour of a process which receives a normal exit is to ignore the signal.
The default behaviour in the two other cases (i.e. abnormal exit) above is to bypass all messages to the
receiving process and to kill it and to propagate the same error signal to the killed process' links. In this
way you can connect all processes in a transaction together using links and if one of the processes exits
```
abnormally, all the processes in the transaction will be killed. As we often want to create a process and link to it at the same time, there is a special BIF, spawn_link which does the same as spawn, but also creates a link to the spawned process. (*manual*).

Now an example of the ping pong example using links to terminate “pong”:

```erlang
-module(tut20).
-export([start/1, ping/2, pong/0]).
ping(N, Pong_Pid) ->
    link(Pong_Pid),
    ping1(N, Pong_Pid).

ping1(0, _) ->
    exit(ping);
ping1(N, Pong_Pid) ->
    Pong_Pid ! {ping, self()},
    receive
        pong ->
            io:format("Ping received pong~n", []),
        end,
    ping1(N - 1, Pong_Pid).
pong() ->
    receive
        {ping, Ping_PID} ->
            io:format("Pong received ping~n", []),
            Ping_PID ! pong,
            pong()
        end.
start(Ping_Node) ->
    PongPID = spawn(tut20, pong, []),
    spawn(Ping_Node, tut20, ping, [3, PongPID]).
```

This is a slight modification of the ping pong program where both processes are spawned from the same start/1 function, where the “ping” process can be spawned on a separate node. Note the use of the spawn_link BIF. “Ping” calls exit(ping) when it finishes and this will cause an exit signal to be sent to “pong” which will also terminate.

It is possible to modify the default behaviour of a process so that it does not get killed when it receives abnormal exit signals, but all signals will be turned into normal messages on the format
{\texttt{'EXIT'}, \texttt{FromPID}, \texttt{Reason}} and added to the end of the receiving processes message queue. This behaviour is set by:

\begin{verbatim}
process_flag(trap_exit, true)
\end{verbatim}

There are several other process flags (*manual*). Changing the default behaviour of a process in this way is usually not done in standard user programs, but is left to the supervisory programs in OTP (but that's another tutorial). However we will modify the ping pong program to illustrate exit trapping.

\begin{verbatim}
-module(tut21).
-export([start/1, ping/2, pong/0]).

ping(N, Pong_Pid) ->
  link(Pong_Pid),
  ping1(N, Pong_Pid).

ping1(0, _) ->
  exit(ping);

ping1(N, Pong_Pid) ->
  Pong_Pid ! \{ping, self()\},
  receive
    pong ->
      io:format("Ping received pong\n", [])
    end,
    ping1(N - 1, Pong_Pid).

pong() ->
  process_flag(trap_exit, true),
  pong1().

pong1() ->
  receive
    \{ping, Ping_PID\} ->
      io:format("Pong received ping\n", []),
      Ping_PID ! pong,
      pong1();
    \{\texttt{'EXIT'}, \texttt{From}, \texttt{Reason}\} ->
      io:format("pong exiting, got \texttt{p\n}, \texttt{\{\texttt{'EXIT'}, \texttt{From}, \texttt{Reason}\}\}}
  end.

start(Ping_Node) ->
  PongPID = spawn(tut21, pong, []),
  spawn(Ping_Node, tut21, ping, [3, PongPID]).
\end{verbatim}

\begin{verbatim}
(s1@bill)1> tut21:start(s2@gollum).
<3820.39.0>
Pong received ping
Ping received pong
Pong received ping
Ping received pong
\end{verbatim}
Pong received ping
Ping received pong
pong exiting, got {'EXIT',<3820.39.0>,ping}

1.4.3 The Larger Example with Robustness Added

Now we return to the messenger program and add changes which make it more robust:

%%% Message passing utility.
%%% User interface:
%%% login(Name)
%%% One user at a time can log in from each Erlang node in the
%%% system messenger: and choose a suitable Name. If the Name
%%% is already logged in at another node or if someone else is
%%% already logged in at the same node, login will be rejected
%%% with a suitable error message.
%%% logoff()
%%% Logs off anybody at at node
%%% message(ToName, Message)
%%% sends Message to ToName. Error messages if the user of this
%%% function is not logged on or if ToName is not logged on at
%%% any node.
%%% One node in the network of Erlang nodes runs a server which maintains
%%% data about the logged on users. The server is registered as "messenger"
%%% Each node where there is a user logged on runs a client process registered
%%% as "mess_client"
%%% Protocol between the client processes and the server
%%% ----------------------------------------------------
%%% To server: {ClientPid, logon, UserName}
%%% Reply {messenger, stop, user_exists_at_other_node} stops the client
%%% Reply {messenger, logged_on} logon was successful
%%% When the client terminates for some reason
%%% To server: {'EXIT', ClientPid, Reason}
%%% To server: {ClientPid, message_to, ToName, Message} send a message
%%% Reply: {messenger, stop, you_are_not_logged_on} stops the client
%%% Reply: {messenger, receiver_not_found} no user with this name logged on
%%% Reply: {messenger, sent} Message has been sent (but no guarantee)
%%% To client: {message_from, Name, Message},
%%% Protocol between the "commands" and the client
%%% Started: messenger:client(Server_Node, Name)
%%% To client: logoff
%%% To client: {message_to, ToName, Message}
%% Configuration: change the server_node() function to return the node name of the node where the messenger server runs

-module(messenger).
-export([start_server/0, server/0, logon/1, logoff/0, message/2, client/2]).

%%% Change the function below to return the name of the node where the messenger server runs
server_node() -> messenger@super.

%%% This is the server process for the "messenger" 
%%% the user list has the format [{ClientPid1, Name1},{ClientPid22, Name2},...]
server() ->
  process_flag(trap_exit, true),
  server([]).

server(User_List) ->
  receive
    {From, logon, Name} ->
      New_User_List = server_logon(From, Name, User_List),
      server(New_User_List);
    {'EXIT', From, _} ->
      New_User_List = server_logoff(From, User_List),
      server(New_User_List);
    {From, message_to, To, Message} ->
      server_transfer(From, To, Message, User_List),
      io:format("list is now: ~p~n", [User_List]),
      server(User_List)
  end.

%%% Start the server
start_server() ->
  register(messenger, spawn(messenger, server, [])).

%%% Server adds a new user to the user list
server_logon(From, Name, User_List) ->
  case lists:member(Name, User_List) of
    true ->
      From ! {messenger, stop, user_exists_at_other_node}, %reject logon
      User_List;
    false ->
      From ! {messenger, logged_on},
      link(From),
      [{From, Name} | User_List] %add user to the list
  end.

%%% Server deletes a user from the user list
server_logoff(From, User_List) ->
  lists:keydelete(From, 1, User_List).
%%% Server transfers a message between users
server_transfer(From, To, Message, User_List) ->
  % check that the user is logged on and who he is
  case lists:keysearch(From, 1, User_List) of
    false ->
      From ! {messenger, stop, you_are_not_logged_on};
    {value, {_, Name}} ->
      server_transfer(From, Name, To, Message, User_List)
  end.

%%% If the user exists, send the message
server_transfer(From, Name, To, Message, User_List) ->
  % Find the receiver and send the message
  case lists:keysearch(To, 2, User_List) of
    false ->
      From ! {messenger, receiver_not_found};
    {value, {ToPid, To}} ->
      ToPid ! {message_from, Name, Message},
      From ! {messenger, sent}
  end.

%%% User Commands
logon(Name) ->
  case whereis(mess_client) of
    undefined ->
      register(mess_client, 
        spawn(messenger, client, [server_node(), Name]));
    _ -> already_logged_on
  end.

logoff() ->
mess_client ! logoff.

message(ToName, Message) ->
  case whereis(mess_client) of
    undefined ->
      not_logged_on;
    _ -> mess_client ! {message_to, ToName, Message},
        ok
  end.

%%% The client process which runs on each user node
client(Server_Node, Name) ->
  {messenger, Server_Node} ! {self(), logon, Name},
  await_result(),
  client(Server_Node).

client(Server_Node) ->
  receive
    logoff ->
      exit(normal);
Chapter 1: Getting Started With Erlang

{message_to, ToName, Message} ->
    {messenger, Server_Node} ! {self(), message_to, ToName, Message},
    await_result();
{message_from, FromName, Message} ->
    io:format("Message from "p: "p"n", [FromName, Message])
end,
client(Server_Node).

%%% wait for a response from the server
await_result() ->
    receive
        {messenger, stop, Why} -> % Stop the client
            io:format(""p"n", [Why]),
            exit(normal);
        {messenger, What} -> % Normal response
            io:format(""p"n", [What])
            after 5000 ->
                io:format("No response from server"n", []),
                exit(timeout)
        end.

We have added the following changes:
The messenger server traps exits. If it receives an exit signal, {EXIT, From, Reason} this means that a client process has terminated or is unreachable because:

- the user has logged off (we have removed the “logoff” message),
- the network connection to the client is broken,
- the node on which the client process resides has gone down, or
- the client processes has done some illegal operation.

If we receive an exit signal as above, we delete the tuple, {From, Name} from the servers User List using the server_logoff function. If the node on which the server runs goes down, an exit signal (automatically generated by the system), will be sent to all of the client processes: {EXIT, MessengerPID, noconnection} causing all the client processes to terminate.

We have also introduced a timeout of five seconds in the await_result function. I.e. if the server does not reply within five seconds (5000 ms), the client terminates. This is really only needed in the logon sequence before the client and server are linked.

An interesting case is if the client was to terminate before the server links to it. This is taken care of because linking to a non-existent process causes an exit signal, {EXIT, From, noproc}, to be automatically generated as if the process terminated immediately after the link operation.

1.5 Records and Macros

Larger programs are usually written as a collection of files with a well defined interface between the various parts.
1.5.1 The Larger Example Divided into Several Files

To illustrate this, we will divide the messenger example from the previous chapter into five files:

- `mess_config.hrl`: header file for configuration data
- `mess_interface.hrl`: interface definitions between the client and the messenger
- `user_interface.erl`: functions for the user interface
- `mess_client.erl`: functions for the client side of the messenger
- `mess_server.erl`: functions for the server side of the messenger

While doing this we will also clean up the message passing interface between the shell, the client and the server and define it using records, we will also introduce macros.

```erlang
%%%----FILE mess_config.hrl----

%%% Configure the location of the server node,
-define(server_node, messenger@super).

%%%----END FILE----

%%%----FILE mess_interface.hrl----

%%% Message interface between client and server and client shell for
%%% messenger program

%%% Messages from Client to server received in server/1 function.
-record(logon, {client_pid, username}).
-record(message, {client_pid, to_name, message}).
%% 'EXIT', ClientPid, Reason) (client terminated or unreachable.

%%% Messages from Server to Client, received in await_result/0 function
-record(abort_client, {message}).
%%% Messages are: user_exists_at_other_node,
%%% you_are_not_logged_on
-record(server_reply, {message}).
%%% Messages are: logged_on
%%% receiver_not_found
%%% sent (Message has been sent (no guarantee)
%%% Messages from Server to Client received in client/1 function
-record(message_from, {from_name, message}).

%%% Messages from shell to Client received in client/1 function
%%% spawn(mess_client, client, [server_node(), Name])
-record(message_to, {to_name, message}).
%%% logoff

%%%----END FILE----

%%%----FILE user_interface.erl----

%%% User interface to the messenger program
%%% login(Name)
```

Getting Started with Erlang
One user at a time can log in from each Erlang node in the system messenger: and choose a suitable Name. If the Name is already logged in at another node or if someone else is already logged in at the same node, login will be rejected with a suitable error message.

logoff()  
Logs off anybody at at node

message(ToName, Message)  
sends Message to ToName. Error messages if the user of this function is not logged on or if ToName is not logged on at any node.

-module(user_interface).
-export([logon/1, logoff/0, message/2]).
-include("mess_interface.hrl").
-include("mess_config.hrl").

logon(Name) ->
  case whereis(mess_client) of
    undefined ->
      register(mess_client, spawn(mess_client, client, [?server_node, Name]));
    _ -> already_logged_on
  end.

logoff() ->
  mess_client ! logoff.

message(ToName, Message) ->
  case whereis(mess_client) of  
    undefined ->
      not_logged_on;
    _ -> mess_client ! #message_to{to_name=ToName, message=Message}, ok
  end.

----END FILE----

----FILE mess_client.erl----

The client process which runs on each user node

-module(mess_client).
-export([client/2]).
-include("mess_interface.hrl").

client(Server_Node, Name) ->
  {messenger, Server_Node} ! #logon{client_pid=self(), username=Name},
  await_result(),
  client(Server_Node).
client(Server_Node) ->
    receive
      logoff ->
        exit(normal);
      #message_to{to_name=ToName, message=Message} ->
        {messenger, Server_Node} !
      #message{client_pid=self(), to_name=ToName, message=Message},
        await_result();
      {message_from, FromName, Message} ->
        io:format("Message from ~p: ~p", [FromName, Message])
    end,
    client(Server_Node).

%%% wait for a response from the server
await_result() ->
    receive
      #abort_client{message=Why} ->
        io:format("~p", [Why]),
        exit(normal);
      #server_reply{message=What} ->
        io:format("~p", [What])
      after 5000 ->
        io:format("No response from server", []),
        exit(timeout)
    end.

%%%----END FILE---

%%%----FILE mess_server.erl----

%%% This is the server process of the messneger service
-module(mess_server).
-export([start_server/0, server/0]).
-include("mess_interface.hrl").

server() ->
    process_flag(trap_exit, true),
    server([]).

%%% the user list has the format [{ClientPid1, Name1},{ClientPid22, Name2},...]
sERVER(User_List) ->
    io:format("User list = ~p", [User_List]),
    receive
      #logon{client_pid=From, username=Name} ->
        New_User_List = server_logon(From, Name, User_List),
        server(New_User_List);
      {'EXIT', From, _} ->
        New_User_List = server_logoff(From, User_List),
        server(New_User_List);
      #message{client_pid=From, to_name=To, message=Message} ->
        server_transfer(From, To, Message, User_List),
        server(User_List)
%% Start the server
start_server() ->
    register(messenger, spawn(?MODULE, server, [])).

%%% Server adds a new user to the user list
server_logon(From, Name, User_List) ->
    %% check if logged on anywhere else
    case lists:keymember(Name, 2, User_List) of
        true ->
            From ! #abort_client{message=user_exists_at_other_node},
                   User_List;
        false ->
            From ! #server_reply{message=logged_on},
            link(From),
            [{From, Name} | User_List] %add user to the list
    end.

%%% Server deletes a user from the user list
server_logoff(From, User_List) ->
    lists:keydelete(From, 1, User_List).

%%% Server transfers a message between user
server_transfer(From, To, Message, User_List) ->
    %% check that the user is logged on and who he is
    case lists:keysearch(From, 1, User_List) of
        false ->
            From ! #abort_client{message=you_are_not_logged_on};
        {value, {_, Name}} ->
            server_transfer(From, Name, To, Message, User_List)
    end.

%%% If the user exists, send the message
server_transfer(From, Name, To, Message, User_List) ->
    %% Find the receiver and send the message
    case lists:keysearch(To, 2, User_List) of
        false ->
            From ! #server_reply{message=receiver_not_found};
        {value, {ToPid, To}} ->
            ToPid ! #message_from{from_name=Name, message=Message},
            From ! #server_reply{message=sent}
    end.

%%%----END FILE---

1.5.2 Header Files
You will see some files above with extension .hrl. These are header files which are included in the .erl files by:

-include("File_Name").
for example:

-include("mess_interface.hrl").

In our case above the file is fetched from the same directory as all the other files in the messenger example. (*manual*).

.hrl files can contain any valid Erlang code but are most often used for record and macro definitions.

### 1.5.3 Records

A record is defined as:

-`record(name_of_record,{field_name1, field_name2, field_name3, ......}).`

For example:

-`record(message_to,{to_name, message}).`

This is exactly equivalent to:

{message_to, To_Name, Message}

Creating record, is best illustrated by an example:

#message_to{message="hello", to_name=fred}

This will create:

{message_to, fred, "hello"}

Note that you don't have to worry about the order you assign values to the various parts of the records when you create it. The advantage of using records is that by placing their definitions in header files you can conveniently define interfaces which are easy to change. For example, if you want to add a new field to the record, you will only have to change the code where the new field is used and not at every place the record is referred to. If you leave out a field when creating a record, it will get the value of the atom undefined. (*manual*)

Pattern matching with records is very similar to creating records. For example inside a `case` or `receive`:

#message_to{to_name=ToName, message=Message} ->

is the same as:

{message_to, ToName, Message}
1.5.4 Macros

The other thing we have added to the messenger is a macro. The file mess_config.hrl contains the definition:

```
%%% Configure the location of the server node,
-define(server_node, messenger@super).
```

We include this file in mess_server.erl:

```
-include("mess_config.hrl").
```

Every occurrence of `server_node` in mess_server.erl will now be replaced by `messenger@super`.

The other place a macro is used is when we spawn the server process:

```
spawn(?MODULE, server, []).
```

This is a standard macro (i.e. defined by the system, not the user). `?MODULE` is always replaced by the name of current module (i.e. the `-module` definition near the start of the file). There are more advanced ways of using macros with, for example parameters (*manual*).

The three Erlang (.erl) files in the messenger example are individually compiled into object code file (.beam). The Erlang system loads and links these files into the system when they are referred to during execution of the code. In our case we simply have put them in the same directory which is our current working directory (i.e. the place we have done "cd" to). There are ways of putting the .beam files in other directories.

In the messenger example, no assumptions have been made about what the message being sent is. It could be any valid Erlang term.
